BIOTECHNOLOGY DEGRADATION AND MITIGATION OF OFFSHORE OIL SPILLS, PHASE 1. MAIN REPORT: TECHNOLOGY TO ENHANCE BIODECRADATION OF OIL SPILLS STATE OF THE ART AND PERSPEC-TIVES EQUI TECHNOLOGY DEVEL OPMENS TIVES FOR TECHNOLOGY DEVELOPMENT. Norsk Petroleumsinstitutt, Oslo.

T. Bakke, T. Briseid, G. Eidsa, R. G. Lichtenthaler, and E. Nordgaard.

Available from the National Technical Information Service, Springfield, VA. 22161, as DE88-757318. Price codes: A03 in paper copy, A01 in microfiche. Report No. NIVA-O-86095, December 4, 1986.

Descriptors: \*Biodegradation, \*Biotechnology, \*Cleanup, \*Marine environment, \*Oil spills, \*Water pollution treatment, Bacteria, Biological treatment, Dispersants, Fertilizers, Nitrogen, Oil pollution, Phosphorus.

Many marine microorganisms have the ability to metabolize and mineralize oil. Bacteria are, in genmetabolize and mineralize oil. Bacteria are, in gen-eral, regarded as the most important group, as are fungi, yeasts, cyanobacteria and to some extent microalgae able to degrade oil. A potential for biodegradation of oil therefore exists in most marine environments. Biodegradation occurs at the oil-water interface. Dispersion (physical or chemi-cal) of oil in the water will greatly increase this interface as well as the surface-to-volume ratio of the oil, and is therefore a necessary condition for significant biodegradation to occur. Means to insignificant biodegradation to occur. Means to in-crease oil-in-water dispersion (dispersants, emulsion inhibitors, and other surfactants) are thus the most promising starting points for development of the desired biodegradation technology. In general, the rate of biological processes decrease with decreasing temperature. The microorganisms need mineral nutrients such as nitrogen, phosphorus, and iron to utilize oil. Application of organic N and iron to utilize oil. Application of organic is and P containing nutrients is a way to provide these nutrients, especially with 'lipophilic fertilizers' which tend to adhere to or mix with the oil, and are thus readily available for utilization by the microorganisms on the oil. One basic philosophy for the research needed to develop oil combat technology, on the basis of biodegradation, is therefore to combine technology to disperse the oil

### Group 5G-Water Quality Control

(dispersants and emulsion inhibitors) with addition of oil soluble fertilizers. The advantage of adding microbial cultures (mixed or single species) as a means to accelerate the oil degradation rate is uncertain. It is also doubtful if 'superbugs', or uncertain. It is also doubtful if 'superbugs', or specialized bacteria produced through genetic engineering, can meet requirements of effectiveness, adaptivity to storage and various ecological regimes, and lack of pathogenicity. Sorbents have proven to be efficient in trapping oil for easy untake by mechanical means but due to the limited uptake by mechanical means, but due to the limited supply of oxygen and nutrients in the oil-sorbent material, they are regarded as less favorable for oil degradation than dispersants and emulsion inhibitors. #### SUPERFUND RECORD OF DECISION: REICH FARMS, NJ.

FARMS, NJ. Environmental Protection Agency, Washington, DC. Office of Emergency and Remedial Response. Available from the National Technical Information Service, Springfield, VA. 22161, as PB89-206254. Price codes: A06 in paper copy, A01 in microfiche. Report No. EPA/ROJ/R02-88/070, September 1988. 104p, 4 fig, 6 tab, append.

Descriptors: \*Cleanup operations, \*Groundwater pollution, \*Site remediation, \*Superfund, \*Water pollution sources, Air stripping, Aquifers, Costs, Excavation, New Jersey, Organic compounds, Tetrachitoreethylene, Trichloroethane, Volatile organic compounds, Water pollution treatment.

The Reich Farm site is located in Dover Township, Ocean County, New Jersey. The site is ap-proximately one mile northeast of the Toms River, but no floodplains or wetlands are affected by the but no floodplains or wetlands are affected by the site. In August 1971, a portion of the land was rented for the temporary storage of used 55-gal drums. Most of the drums had Union Carbide Corporation (UCC) markings on them, with labels reading 'tar pitch,' 'lab waste solvent,' 'blend of resin and oil,' and 'solvent wash of process stream' among others. The site first came to the attention of the New Jersey Superior Court when the Reichs filed suit against UCC and other previous owners. UCC undertook drum removal and completed the work in March 1972. In June 1974, another 51 drums and approximately 1,100 cu yd another 51 drums and approximately 1,100 cu yd of contaminated soil and trenched wastes were removed from the site, but residents near the site had already complained about an unusual taste and odor in their well water. Based on results of an extensive sampling program, the Dover Township Board of Health ordered 148 private wells closed, and established a zoning ordinance restricting groundwater use in the area of the Reich Farm. The volume of contaminated soil remaining at the site is estimated to be 2,010 cu yd. The primary contaminants of concern affecting the groundwater and soils are volatile organic compounds (VOCs) including 1,1,1-trichloroethane (TCA), trichloroethene, tetrachloroethylene, and semi-volatile organic compounds. The selected remedial action for odor in their well water. Based on results of an ganic compounds. The selected remedial action for this site includes: additional groundwater sampling to further delineate the leading edge of the con-taminant plume and additional soil sampling to support existing data on contaminants of concern support existing data on contaminants of concern at the site; groundwater pump and treatment using air stripping and carbon adsorption with reinjec-tion of the treated water back into the aquifer; and excavation and storage of surface soils on-site, excavation and storage of surface soils on-site, which do not require remediation. The estimated present worth cost for this remedial action is \$5,832,000, which includes annual operation and maintenance costs of \$419,550. (Lantz-PTT) W91-10743

#### AKE LANSING DREDGING EVALUATION STUDY, 1978-1984.

Michigan Dept. of Natural Resources, Lansing. R. Mikula.

Available from the National Technical Information Service, Springfield, VA 22161, as PB89-208763. Price codes: A06 in paper copy, A01 in microfiche. March, 1985. 104p, 17 fig, 7 tab, 22 ref, 2 append.

Descriptors: \*Dredging, \*Ecological effects, \*Lake Lansing, \*Lake restoration, \*Water quality, Arsenic, Chlorophyll a, Eutrophic lakes, Kjeldahl

nitrogen, Limnology, Mercury, Michigan, Nitrates, Nitrites, Oxygen, Phytoplankton, Species composition.

Lake Lansing is located seven miles east of Lansing, Michigan. Prior to dredging the lake was eutrophic, had a surface area of 182 hectares (approximately 450 acres), a maximum depth of 11 meters (35 feet), and a mean depth of somewhere between 2.1 and 2.3 meters (7.0 to 7.5 feet). Between May, 1978 and August, 1983 approximately 1.6 million cu yd of soft sediment were removed from the lake and 220,890 cu yd of sand were redistributed within the lake. Surface area and maximum depth remained the same after dredging as before, but the mean depth increased to 2.7 meters (9.0 feet). Comparison of pre-dredging and post-dredging data reveals an increase in transparency and substantial reductions in in-lake phosphorus and chlorophyll a. Some reduction in total rus and chlorophyll a. Some reduction in total Kjeldahl nitrogen occurred. Changes in nitrate + nitrite and oxygen depletion were not evident. Trophic status of Lake Lansing improved from a highly eutrophic condition to a meso-eutrophic condition. Heavy metals, specifically arsenic and mercury, were not remobilized during dredging. Benthic macroinvertebrate communities did not change in composition, but did exhibit an increase in number of individuals after dredging. Composiin number of individuals after dredging. Composi in number of individuals after dredging. Composi-tion of the fish community was poor prior to and after dredging. Phytoplankton communities dis-played a seasonal diversity of types which varied in patterns typical of mesotrophic and/or eutro-phic lakes. Zooplankton populations did not change in composition, but did exhibit a decrease in number of individuals after dredging. Additional surveys will be conducted by the Michigan De-partment of Natural Resources prior to implement-ing management strategies. (Lantz-PTT) W91-10748

### SUPERFUND RECORD OF DECISION. MID-STATE DISPOSAL LANDFILL, WI. Environmental Protection Agency, Washington,

DC

DC. Available from the National Technical Information Service, Springfield, VA 22161, as PB89-189559. Price Codes: A04 in paper copy, A01 in microfiche. Report No. EPA/ROD/RO5-88/076, September 1988. 55p, 4 fig, 7 tab.

Descriptors: \*Cleanup operations, \*Landfills, \*Site remediation, \*Superfund, \*Water pollution sources, \*Wisconsin, Benzenes, Costs, Drainage, Groundwater pollution, Leachates, Monitoring, Path of pollutants, Tetrachlorethylene, Trichloroethane, Volatile organic compounds, Waste capcing.

The Mid-State Disposal (MSD) site is an abandoned municipal and industrial waste landfill located in central Wisconsin, about 4 miles northeast of Stratford. Site runoff enters nearby waterways in-cluding the Rock Creek and Eau Plune River via unnamed tributaries. Additionally, groundwater from the site is believed to be discharging into a ravine 500 feet south of the site. MSD conducted landfilling operations from 1970-1979, receiving municipal, industrial and commercial wastes as municipal, industrial and commercial wastes as well as construction and demolition debris. Specific wastes received included papermill sludges, asbestos dust, solvents, pesticides, paint sludges and metals. In 1979, Weyerhaeuser Company, a generator of waste disposed at the facility, agreed to properly abandon the facility. The pond leachate was removed, and the three waste disposal areas were covered. Leachate collection systems were installed in late 1979 for both the sludge lagoon and the Interim Expansion area; only the leachate and the Interim Expansion area; only the leachate collected from the latter is currently removed and treated off-site. Subsequent investigations revealed that groundwater has been contaminated by leachate percolating from the waste disposal areas and the leachate pond down to the underlying aquifer. The primary contaminants of concern affecting the groundwater, surface water and soil are volatile organic compounds including benzene, tetrachlor-oethylene, and trichloroethane, and metals. The selected remedial action for this site includes: installation of new soil/clay caps for the lagoon and landfills; site monitoring that includes groundwater, surface water, and landfill gas monitoring; off-

site groundwater monitoring; provision of an alter-nate water supply for nearby residences; improve-ment of surface water drainage; leachate and ponded water collection and offsite treatment; and, in situ solidification/stabilization of sludge as necessary for cap support. The estimated present worth for this remedial action is \$16,000,000 with annual operation and maintenance of \$22,000 for the first year, and \$100,000 for years 2-30. (Lantz-

### AMBIENT WATER QUALITY CRITERIA FOR AMMONIA (SALTWATER)-1989.

Environmental Protection Agency, Washington, DC. Office of Water Regulations and Standards. Available from the National Technical Information Service, Springfield, VA 22161, as PB89-195242. Price codes: A05 in paper copy, A01 in microfiche. EPA Report 440/5-88-004, April 1989. 76p, 7 tab, 146 ref, 2 append.

Descriptors: \*Ammonia, \*Ecotoxicology, \*Saline water, \*Standards, \*Water pollution control, \*Water quality, Aquatic life, Estuaries, Marine environment, Toxicity.

Ammonia is a common and highly toxic pollutant which, in sufficient quantities, will adversely affect aquatic organisms. The ammonia criteria document for salt water will allow establishment of regulatory standards for ammonia discharge into estuaries, near coastal zones and oceans. Possible adverse invects in highly sensitive and abundant aries, near coastan zones and oceans. Possible activerse impacts in highly sensitive and abundant ecosystems such as estuaries make regulation particularly important. Except where locally important species are very sensitive, salt water aquatic organisms should not be affected unacceptably if. (1) the criterion continuous concentration for unionized ammonia does not exceed 0.035 mg/L more than once every three years on average more than once every three years on average (chronic exposure expressed as a 4-day average); and (2) the criterion maximum concentration (acute exposure expressed as a one-hour average) does not exceed 0.233 mg/L more than once every three years on the average. Because many salt water organisms have a narrow range of acute sensitivity to ammonia, these criteria will probably hear evertexitie as intended cally when the exposure of the contraction be as protective as intended only when the magnitude and/or durations of criteria exceedence are appropriately small. It is particularly important to recognize that variability of exposure will be relatively high in tidal saltwater ecosystems due to changes in available dilution as the tide recedes, and incomplete flushing of estuaries. (Author's abstract) W91-10750

## SUPERFUND RECORD OF DECISION: KIN-BUC LANDFILL, NJ.

Environmental Protection Agency, Washington,

Available from the National Technical Information Service, Springfield, VA 22161, as PB89-189500. Price codes: A05 in paper copy, A01 in microfiche. EPA Report ROD/RO2-88/068, September 1988. 70p, 6 fig, 5 tab, 5 append.

Descriptors: \*Cleanup operations, \*Groundwater pollution, \*Kin-Buc Landfill, \*New Jersey, \*Raritan River, \*Site remediation, \*Superfund, \*Water pollution sources, Arsenic, Benzenes, Costs, Heavy metals, Incineration, Lead, Monitoring, Polychlorinated biphenyls, Toluene, Volatile organic compounds, Waste capping.

The 220-acre Kin-Buc Landfill consists of a number of inactive industrial and municipal waste number of inactive industrial and municipal waste disposal areas and is located in the Raritan River 100-year flood plain and within a coastal zone in Edison Township, Middlesex County, New Jersey. Landfill operations were conducted between 1947 and 1977. According to site records, an estimated 70 million gallons of liquid wastes, including 3 million gallons of oily waste and over 1 million tons of solid waste, were disposed of between 1973 and 1976 alone. Examples of wastes received in-clude solvents, waste oils, paint sludges, cyanides, metal stripping wastes and paint thinners. Site ac-tivities included burying and compacting contained

## Water Quality Control—Group 5G

wastes in Kin-Buc II, and discharging hazardous liquid wastes into bulldozed pits at the top of Kin-Buc I. EPA began investigations in January 1976 and detected the discharge of hazardous substances from the facility. In February 1980, EPA began cleanup activities consisting of collection, treatment, and disposal of Pool C leachate; a drum neuti, and utsposal of root reachate; a drum reduction program; oil-phase leachate collection and onsite storage; and aqueous-phase leachate pretreatment, removal, and offsite treatment. In September 1980, Kin-Buc, Inc. was ordered to cap Kin-Buc I and II. The primary contaminants of concern affecting the groundwater, surface water, sediments, soil and air are: volatile organic compounds including benzene and toluene, other organics including polycyclic aromatic hydrocarbons and polychlorinated biphenyls, and metals including arsenic and lead. The selected remedial action for this site includes: installation of a slurry wall surrounding the site; RCRA capping over Kin-Buc II; collection of approximately 3 million gallons of oily-phase leachate with off-site incineration and residual disposal; collection and on-site biological or carbon treatment of aqueous-phase leachate and contaminated groundwater and dewatering of residual sludges and offsite disposal; and, groundwatreduction program; oil-phase leachate collection contaminated groundwater and dewatering of re-sidual sludges and offsite disposal; and, groundwat-er monitoring. The estimated present worth cost for this remedial action is between \$16,290,000 and \$16,635,000 with annual O&M varying from \$848,000 (year 1) to \$405,000 (years 12-20). SUPERFUND RECORD OF DECISION: PALMERTON ZINC PILE, PA.

Environmental Protection Agency, Washington,

DC. Available from the National Technical Information Service, Springfield, VA 22161, as PB89-204762. Price codes: A04 in paper copy, A01 in microfiche. EPA Report ROD/RO3-88/063, September 1988. 60p, 4 fig, 1 tab, 2 append.

Descriptors: \*Cleanup operations, \*Palmerton Zinc Site, \*Pennsylvania, \*Site remediation, \*Superfund, \*Water pollution sources, Cadmium, Diversion channels, Groundwater pollution, Heavy metals, Leachates, Lead, Monitoring, Vegetation, Waste capping, Wastewater lagoons, Wetlands wastewater treatment, Zinc.

The Palmerton Zinc site is composed of two locations in the Borough of Palmerton, Carbon tions in the borough or raimerton, Carooni County, Pennsylvania. Smelting operations have been conducted at two locations, a west smelter and an east smelter, flanking the Town of Palmer-ton, which is located at the confluence of the ton, which is located at the commence of the Lehigh River and Aquashicola Creek. The drain-age pattern in the site area is toward Aquashicola Creek, designated a warm water fishery by the State of Pennsylvania, which flows into Lehigh River. Smelting operations were conducted in the west plant from 1898 to 1987, and in the east plant from 1911 to present. Between 1898 and 1987 process residue and other plant wastes (as well as municipal waste until 1970) were disposed of on Cinder Bank, a 2.5-mile, 2,000-acre waste pile lo-cated behind the east plant at the base of the Blue Mountains. Cinder Bank contains approximately 27.5 million tons of leachable metals including lead, zinc, and cadmium, as well as carbonaceous material. Large blocks of residue crack and break off, allowing rapid infiltration of runoff during periods of rain and snow melt, resulting in contaminated leachate percolating down to the groundwater and seeping out of Cinder Bank. This remedial action addresses Cinder Bank. Additional areas of contamination as well as groundwater and surface water contamination will be addressed in subsequent remedial actions. The primary contami-nants of concern affecting the sediments, groundwater, and surface water are metals including cad-mium, lead and zinc. The selected remedial action for this site includes: slope modification, capping, and application of a vegetative cover on Cinder Bank; construction of surface water diversion channels; surface water and leachate collection and treatment using lime-activated filtration lagoons and/or constructed wetlands; implementation of an inspection, monitoring, and maintenance plan; and wetlands restoration measures, if necessary. The estimated present worth cost for this remedial action will be in excess of \$2,861,800; however, the exact figure will not be known until agreement is reached on the extent of remediation during reme-dial design. (Author's abstract)

SUPERFUND RECORD OF DECISION: SOUTH VALLEY/EDMUNDS STREET, NM. Environmental Protection Agency, Washington,

DC. Available from the National Technical Information Service, Springfield, VA 22161, as PB90-107558. Price codes: A03 in paper copy, A01 in microfiche. EPA Report ROD/R06-89/048, March 1989. 41p, 3 fig, 1 tab, 3 append.

Descriptors: \*Groundwater quality, \*Site remediation. \*South Valley Superfund Site, \*Superfund, \*Water pollution sources, Cleanup operations, Military reservations, New Mexico, Soil contami-

The South Valley/Edmunds Street site is a portion of the South Valley Superfund site-a large area in the southern part of the city of Albuquerque, New Mexico. The site has been divided into operable Mexico. The site has been divided into operable units to address soil and groundwater contamination resulting from current and historical industrial practices. The operable units include Edmunds Street Ground Water, Former Air Force Plant 83/GE, San Jose-6, and the final operable unit, Edmunds Street Source Control. Potential sources of groundwater contamination within the Edmunds Street property have been identified, but primary focus has been given to a drainage pit area which receives most of the drainage from the property. Investigations in all of the suspected potential contaminant source areas. however, revealed little soil taminant source areas, however, revealed little soil contamination. Even if further migration of concontamination. Even if further migration of con-taminants to groundwater occurs, the groundwater treatment system developed in the previous Ed-munds Street Ground Water operable unit will be sufficient to address these concerns. There are no contaminants of concern affecting the soil at this site. The selected remedial response for this final operable unit is no further action. Based on samoperable unit is no further action. Based on sampling data, the soil has been determined to contain contaminant levels below hazardous contaminant concentration limits and poses no risk to human health or the environment. The only further activineattn or the environment. The only further activi-ties anticipated at the site are sampling of soil gases in the drainage pit area following the groundwater remedial action, and the precautions necessary to prevent any disturbance of drainage pit soils during the groundwater remediation. There are no remedial or O&M costs associated with this opera-ble unit. (Author's abstract) W91-10758

SUPERFUND RECORD OF DECISION: CEL-ANESE FIBERS OPERATIONS, NC.

Environmental Protection Agency, Washington,

Available from the National Technical Information Service, Springfield, VA 22161, as PB89-196729. Price codes: A05 in paper copy, A01 in microfich. EPA Report ROD/RO4-88/038, March 1988. 77p, 4 fig, 3 tab, 3 append.

Descriptors: \*Cleanup operations, \*Groundwater pollution, \*Industrial wastewater, \*North Carolina, \*Site remediation, \*Superfund, Adsorption, Adsorpti na, 'Sale remediation, 'Superintin, Adsorption, Air stripping, Benzenes, Biological treatment, Buffalo Creek, Chemical precipitation, Chromium, Costs, Phenols, Tetrachloroethylene, Volatile organic compounds, Water pollution sources.

The 450-acre Celanese Fiber Operations (CFO) site is occupied by a polyester raw-material production facility, and is located in Cleveland County, one mile north of Earl, North Carolina. The plant began operations in 1960 as Fibers Industries, Inc, manufacturing polyester polymer chip and filament yarn using the chemicals dimeth-yl terephthalate and ethylene glycol. Celanese Corporation bought the facility in 1983. The CFO waste treatment plant was constructed in phases concurrent with the manufacturing plant. This resulted in the disposal of chemical wastes directly into a drainage ditch during the early years of operation prior to completion of the waste treat-

ment plant. Treated effluent has been discharged to ment plant. Treated effluent has been discharged to Buffalo Creek since the mid-1960s, when CFO completed construction of the treatment plant. In addition to the discharge from the wastewater treatment plant, CFO also discharges alum-treated bandcaster water directly to Buffalo Creek. Several areas around the plant have been used for waste disposal, including old burning pits for normal plant wastes (polyester and trash), a glycol recovery unit sludge burial area, and a former drum storage and staging area (drums contained solutions that failed to polymerize) excavated and backfilled in the mid-1960s, and two soak-away ponds formerly containing treated sanitary sewage. ponds formerly containing treated sanitary sewage. The primary contaminants of concern affecting the groundwater include: volatile organic compounds including benzene and tetrachloroethylene, organics including phenols, and metals including chromium. The selected remedial action for this site includes: groundwater pump and treatment using air stripping, biological treatment, and carbon adsorp-tion (if necessary), followed by discharge to the on-site wastewater treatment plant. If the treat-ment system effluent contains metals, such as chroment system entural contains metals, such as Caro-mium, above allowable discharge levels, the efflu-ent will be treated using chemical precipitation. The estimated present worth cost for this remedial action if \$2,032,000 with estimated present worth O&M of \$1,069,230. (Author's abstract)

MECHANISTIC EVALUATION OF MITIGA-TION OF PETROLEUM HYDROCARBON CONTAMINATION BY SOIL MEDIUM.

McGill Univ., Montreal (Quebec). Geotechnical Research Centre

Research Centre.
R. N. Yong, and S. M. Rao.
Canadian Geotechnical Journal CGJOAH, Vol. 28, No. 1, p 84-91, February 1991. 4 fig. 5 tab, 32 ref. National Sciences and Engineering Research Council of Canada Grant No. A82.

Descriptors: \*Cleanup operations, \*Hydrocarbons, \*Oil pollution, \*Soil contamination, \*Soil mechanics, \*Soil treatment, \*Water pollution treatment, Adsorption, Bonding, Chemical interactions, Clays, Hydraulic conductivity, Permeation, Polymers, Soil physical properties, Solubility, Sorption.

Various in situ chemical treatment technologies are being developed for mitigation of petroleum hydrocarbon contamination. One treatment for restricting the movement of petroleum hydrocarbon stricting the movement of petroleum hydrocarbon (PHC) molecules in the contaminated soil utilizes the sorption-interaction relationships between the petroleum contaminants and the soil substrate. Petroleum hydrocarbons comprise a mixture of non-polar alkanes and aromatic and polycyclic hydrocarbons that have limited solubility in water. The bonding mechanism between the nonpolar PHC's and the clay surface is by way of van der Waals attraction. The adsorption of the nonpolar hydrocarbons by the clay surface occurs only when the carbons by the clay surface occurs only when the solubility of the hydrocarbon molecules in water is solubility of the hydrocarbon molecules in water is exceeded and the hydrocarbons exist in the micellar form. Dilute solutions of hydrocarbons in water, i.e., concentrations of hydrocarbons at or below the solubility limit, have no effect on the hydraulic conductivity of clay soils. Permeation with pure hydrocarbons invariably influences the clay's hydraulic conductivity. To improve the attenuation ability of soils towards PHC's, it is proposed that the soil surface be coated with 'ultra' heavy organic polymers. Adsorption of organic polymers. posed that the soil surface be coated with 'ultra' heavy organic polymers. Adsorption of organic polymers by the clay surface may change the surface properties of the soil from highly hydrophilic (having affinity for water molecules) to organophilic (having affinity for organic molecules). The organic polymers attached to the clay surface are expected to attenuate the PHC molecules by van der Waals attraction, by hydrogen bonding, and also by adsorption into interlayer space in the case of soils containing swelling clavs. (Author's case of soils containing swelling clays. AQUEOUS SURFACTANT WASHING OF RE-SIDUAL OIL CONTAMINATION FROM SIDUAL OIL

General Motors Research Labs., Warren, MI. En-

### Field 5—WATER QUALITY MANAGEMENT AND PROTECTION

## Group 5G-Water Quality Control

vironmental Science Dent Virolmental Science Dept. C. C. Ang, and A. S. Abdul. Ground Water Monitoring Review GWMRDU, Vol. 11, No. 2, p 121-127, Spring 1991. 6 fig, 5 tab,

Descriptors: "Cleanup, "Oil, "Site remediation, "Soil contamination, "Soil treatment, "Surfactants, Dispersion, Experimental design, Rehabilitation, Sand, Soil columns, Solubility, Solute transport,

A laboratory study was conducted to determine the efficiency of different aqueous concentrations of an alcohol ethoxylate surfactant in washing residual levels of an oil (automatic transmission fluid (ATF)) from sandy soil. Five glass columns packed with the soil were prepared in a manner that simulated conditions leading to residual saturation in an actual oil leak. Each of four columns was washed continuously with 28 pore volumes of solution by pumping either 0.0 percent (water), 0.5 percent, 1.0 percent, or 2.0 percent aqueous surfactant solutions through the columns. The fifth column was washed intermittently with 28 pore volumes of a 1.0 percent surfactant solution. Water column was washed intermittently with 28 pore volumes of a 1.0 percent surfactant solution. Water washed only 25.5 percent of the ATF from the column soil, while the 0.5 percent, 1 percent, and 2 percent surfactant solutions washed 55 percent, 60 percent, and 72.8 percent of the ATF, respectively. The distribution of the ATF remaining in the column after washing showed that the ATF removed by water was mainly from the outlet side of the column, while the ATF removed by the 2.0 percent surfactant solution was mainly from the percent surfactant solution was mainly from the inlet side of the column. This observation indicated that different mechanisms were involved; namely, the displacement of oil through the soil-pore space, the dispersion of oil due to reduced surface ten-sion, and the solubilization of oil by surfactant micelles. The results show promising potential for application in the field and will be further investigated in a two-dimensional model aquifer. (Au-

COMPUTER MODELING OF SCALE FORMA-TION DURING TREATMENT OF GROUND WATER IN AIR STRIPPERS.

WATER IN AIR STRIPPERS.
Case Western Reserve Univ., Cleveland, OH.
Dept. of Geological Sciences.
G. Matisoff, and C. Narquis.
Ground Water Monitoring Review GWMRDU,
Vol. 11, No. 2, p 137-144, Spring 1991. 2 fig, 2 tab,

Descriptors: \*Air stripping, \*Computer models, \*Groundwater pollution, \*Model studies, \*Scaling, \*Water pollution treatment, \*Water treatment, Calcium carbonate, Carbon dioxide, Chemical precipitation, Equilibrium, Flow models, Hydrogen ion concentration, Iron, Iron compounds, Oxidation Medicial Securic compounds tion, Volatile organic compounds

During treatment to remove volatile organic com-pounds from contaminated groundwater, inorganic scale sometimes precipitates in an air stripper tower. This leads to increased costs and down-time associated with tower media replacement. In order to determine the kind, quantity, and rate of scale to determine the kind, quantity, and rate of scale formation, the groundwater from five locations in Florida was simulated using an aqueous equilibrium chemistry and flow process model. In all cases the pH of the outflow water is higher than that of the inflow water because of degassing of CO2. This often results in the precipitation of calcium carbonate. The addition of air to reduced groundwater than the control of the c water results in the oxidation of iron and the precipitation of ferric hydroxides. Model estimates of scale formation are about a factor of two to five too high. This indicates that the precipitation reactions do not reach equilibrium within the air strip-per. Future work will require the inclusion of biological fouling and a kinetic expression to ac-count for the observed non-equilibrium. (Author's abstract) W91-10798

DEVELOPMENT AND IMPLEMENTATION OF A REMEDIAL INVESTIGATION WORK PLAN AND DATA MANAGEMENT SYSTEM.

Local governments often face environmental prob-lems that cross political boundaries. The onus for solution falls on the most severely affected jurisdiction, others do nothing until impacted. Resolution tion, others do nothing until impacted. Resolution of these problems requires cooperation across political boundaries which means that local governments must be persuaded first that there is a problem, and second that action is required to solve it. An iterative, low cost methodology has been developed which can supply credible information to help achieve consensus on solutions to environmental problems. These ideas were developed from experience with an evaluation of a waterquality protection program on Keuka Lake (one of the Finger Lakes) in New York State. Local government officials and residents in the watershed the Finger Lakes) in New York State. Local gov-ernment officials and residents in the watershed were concerned with a rapid increase in rooted aquatic vegetation (particularly Myriophyllum spi-catum, Eurasian water milfoil) which was affecting tourism. The lake is bordered by two incorporated tourism. The lake is bordered by two incorporated villages and six towns in two counties; thus, the environmental issue extended across political boundaries. An iterative program-evaluation strategy was developed to provide information in three areas: (1) Assessment of the role of upland sources in lake nutrient loading-eighteen months of stream sampling provided acceptable evidence that upland areas were not a significant nutrient source; (2) Assessment of the role of lakeshore development Assessment of the role of lakesnore development on lake water quality—a survey of septic system data in the Watershed Inspector's records and an in-lake coliform bacteria sampling program indicated that there may be some significant problems associated with failing septic systems; and (3) Determination of residents' attitudes and perceptions because the water quality—a mill survey of regarding lake water quality-a mail survey of property owners showed policy makers in all six

towns that support existed for a watershed district. A committee was elected to develop draft legislation to form a water-quality management district which will address lake-wide issues such as adequacy of septic system regulation, land use, erosion control, and construction activities. BUFFER STRIPS TO PROTECT WATER SUPPLY RESERVOIRS: A MODEL AND REC-OMMENDATIONS

Cook Coll., New Brunswick, NJ. Dept. of Enviental Resou

G. H. Nieswand, R. M. Hordon, T. B. Shelton, B. B. Chavooshian, and S. Blarr.

Water Resources Bulletin WARBAQ, Vol. 26, No. 6, p 959-966, December 1990. 4 fig. 1 tab, 40 ref. New Jersey Department of Environmental Protection Contract No. C29010.

Descriptors: \*Buffer zones, \*Model studies, \*Reservoirs, \*Water pollution control, \*Water pollution prevention, \*Water quality management, \*Water supply, \*Watershed management, Buffer strips, New Jersey, Nonpoint pollution sources, Traveltime, Vegetation effects.

Buffer strips are undisturbed, naturally vegetated zones around water supply reservoirs and their tributaries that are a recognized and integral aspect of watershed management. These strips can be very effective in protecting the quality of public very effective in protecting the quality of public potable water supply reservoirs by removing sediment and associated pollutants, reducing bank erosion, and displacing activities from the water's edge that represent potential sources of nonpoint source pollutant generation. As part of a comprehensive watershed management project for the State of New Jersey, a parameter-based buffer strip model was developed for application to all watersheds above water supply intakes or reservoirs. Input requirements for the model include a combination of slope, width, and time of travel. The application of the model to a watershed in New Jersey with a recommended buffer strip width that ranges from 50 to 300 feet, depending upon a number of assumptions, results in from 6 to 13 percent of the watershed above the reservoir being occupied by the buffer. (Author's abstract) occupied by the buffer. (Author's abstract) W91-10816

BACTERIOPHAGES AS MODEL VIRUSES IN WATER QUALITY CONTROL.
Water Research WATRAG, Vol. 25, No. 5, p 529-

545, May 1991. 1 fig, 2 tab, 162 ref.

Descriptors: \*Bacteriophage, \*Bioindicators, \*Enteroviruses, \*Viruses, \*Water pollution control, \*Water quality control, \*Water treatment, Culturing techniques, Literature review, Path of pollutants, Pollutant identification, Standards.

The potential of using bacteriophages as models for the fate of viruses in natural waters and water treatment is reviewed with special attention to the somatic coliphages, the F-specific RNA phages and phages of Bacteroides fragilis. Enumeration from highly contaminated samples can be achieved by plaque counts or enrichment methods; for less by plaque counts or emicration medicas, to polluted samples a variety of concentration procedures is available, derived mainly from techniques developed for enteroviruses. International standdeveloped for enteroviruses. International st ardization of methods is necessary to promote fur-ther development of the field. Bacteriophages have promise as process indicators for viruses. F-specific RNA bacteriophages are a more homogeneous RNA bacteriophages are a more homogeneous group than somatic coliphages and have generally a greater resistance. The value of somatic coliphages is further limited by their ability to multiply in unpolluted waters. Both groups are an index of sewage contamination rather than fecal contamination, hence their ecology is different from human enteric viruses. Phages of Bacteroides fragilis have been reported to occur exclusively in human feces well that is the source beautiful the statement of the second properties. but little is known about their behavior in water treatment processes. In-situ biological methods offer promise for restorin-stu biological methods offer promise for restor-ing aquifers contaminated by organics; however, the acceptance of in-situ biological restoration methods is highly dependent on the ability to reli-ably predict the efficiency of the treatment proc-ess. A nonsteady-state model has been developed ess. À nonsteady-state model has been developed for the in-situ biostimulation of a microbial population in saturated porous media. The model includes basic processes of microbial growth, utilization of electron donor and acceptor, advective transport, dispersion, and sorption in porous media. Model simulations were compared with results from a series of controlled field experiments at a site where the growth of an indigenous population of methane-utilizing bacteria (methanotrophs) was stimulated by the controlled addition of dissolved methane and oxygen (DO) into a semiconfined aquifer. Simulations provide good matches to the mentane and oxygen (Do) into a semiconined aquifer. Simulations provide good matches to the observed transient uptake of methane and DO, demonstrating that the observed response resulted from the growth of methanotrophs in the test zone. Simulations duplicate results from alternate pulsed addition of methane (electron donor) and oxygen addition of methane (electron donor) and oxygen (electron acceptor) used as a means for distributing microbial growth throughout the test zone. The model permits estimation of changes in microbial population distribution at various stages of the two-year experiment. Temporal changes in modelistlet distribution at various stages of the two-year experiment. Temporal changes in modelisted hieractic parameters indicate that the microbial population evolved to one that more effectively utilized the methane at lower concentrations. These analyses demonstrate that a relatively simple model, which includes basic microbial and transport processes, can be of use in the design and evaluation of in-situ biotreatment processes. The model user, however, must provide judgement in the selection of appropriate input parameters, as well as being aware of model limitations. (Author's abstract) abstract) W91-10955

## SOCIAL AND PRIVATE RETURNS FROM WETLAND PRESERVATION.

Guelph Univ. (Ontario). Dept. of Agricultural Ec-

Guelph Univ. (Ontario). Dept. of Agricultural Economics and Business.

M. Van Vuuren, and P. Roy.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 553-563, 3 to h 1 ref.

Descriptors: \*Environmental protection, \*Land use, \*Ontario, \*Wetlands, Agriculture, Cost-benefit analysis, Economic aspects, Social aspects, Water quality.

Wetlands in southern Ontario are threatened by competition from urban development and agriculture. Using a case study, the economics of wetland preservation in one of the most productive agricultural areas in Canada, which is close to urban centers, is examined. Two kinds of analyses were performed: social and private cost-benefit analyses. The social analysis incorporates benefits and costs to society at large, while the private analysis includes only benefits and costs to the owner of the wetland. There is a great discrepancy between private and social net benefits of wetland preservation. From the point of view of all beneficiaries of tion. From the point of view of all beneficiaries of a wetland, preservation is the better option, par-ticularly for undiked marshes. It appears that the social preservation benefits on a 150 ha diked

## Water Quality Control—Group 5G

marsh does not match the social agricultural benefits. However, this result must be interpreted with great caution. It is most likely that if option value and water purification benefits could be included in the analysis, they would tip the balance in favor of preservation. On the 20 ha diked and 300 ha of preservation. On the 20 ha diked and 300 ha undiked marshes the preservation benefits, excluding option value and water purification benefits, are already large enough to favor preservation. From the wetland owner's point of view, the situation appears quite different. Although preservation does not result in an absolute loss, the owner is much better off reclaiming the wetlands for agriculture. The major reason for this discrepancy is that a great deal of preservation benefits cannot be cantured by the owner. Drainage subsidies and the that a great deal of preservation benefits cannot be captured by the owner. Drainage subsidies and the tax rebate program are other stimuli for reclamation. Since 1986, the full property taxes paid on farmland are rebated by the Province. Recently, a new program has been announced to rebate the taxes on wetlands as well. However, this is not sufficient to tip the balance, as can be seen in this case study. The present value of property taxes over 50 yrs on diked marshes is \$859/ha and on undiked marshes \$623/ha. More innovative approaches are needed to preserve significant existing wetlands. (See also W91-11003) (Lantz-PTT)

#### MANAGEMENT OF IRRIGATION-INDUCED CONTAMINANTS.

Department of the Interior, Washington, DC. Office of Environmental Affairs.

In: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 617-626, 4

Descriptors: \*Ecological effects, \*Irrigation effects, \*Kesterson Reservoir, \*Selenium, \*Water pollution control, Fish, Pesticides, Public health, Sediment contamination, Water quality.

During the last several years there has been in-creasing recognition of the impacts of irrigation drainage water on human health and fish and wild-life resources. In 1983, the U.S. Department of the Interior discovered that elevated levels of selenium in the Kesterson Reservoir in California were caus-ing waterfowl deaths, deformities, and reproduc-tive failures. In other areas, high levels of other trace elements and pesticides have been identified subsequently in water, sediment, plant and animal samples. In response to this situation, the Interior Department initiated the National Irrigation Water Quality Program to identify, evaluate and respond Quality Program to identify, evaluate and respond to irrigation-induced contamination problems in the western United States. Results of recent work has yielded generic knowledge gained collectively from all of the investigations that are relevant to the management of irrigation-induced contaminants. These observations are: (1) that knowledge of geologic sources of trace elements is very important in determining where problems with irrigation induced contamination are likely to exist; (2) meteorological characteristics of an area can be preteorological characteristics of an area can be tion induced contamination are likely to exist; (2) meteorological characteristics of an area can be very meaningful regarding potential for irrigation-induced contamination problems; (3) closed watersheds were found to be an important physical characteristic of locations that may tend to exhibit symptoms of irrigation-induced contamination; (4) at the study areas where concentrations of seleniat the study areas where concentrations of seleni-um were found to be at levels that could adversely affect wildlife reproduction and growth (Kendrick Reclamation Project, Middle Green River, and Tulare Lake study areas), extensive irrigation and drainage activities occur; (5) selenium is the con-stituent of concern most commonly found at ele-vated concentrations in wetland ecological systems receiving irrigated drainage water; (6) concentra-tions of analytes were found to vary widely on a

Recent investigations have shown that crushed limestone can be used effectively and most eco-nomically to neutralize acidic streams. A treatment station for acidic streams is designed using a selffeeding rotary limestone tumbling drum activated by the stream flow. The main features included a oy the stream flow. The main features included a storage bin and hopper, a feeding mechanism, and some means of metering and transporting the lime-stone aggregates from the storage unit to the tum-bling drum. The station can operate unattended for seven to ten days while being supplied continuous-ly at the required rate from a storage bin. In a pilot treatment station at Otter Creek, West Virginia, such a system was found to be 600% more effective than the batch-loaded drum while requiring tive than the batch-loaded drum while requiring only one-sixth of the water flow requirements. The proper design of the tumbling drum requires careful consideration of certain parameters: the rate of flow and acid level of the stream, the aggregate feed rate and size, and the RPM of the drum. ENVIRONMENTAL CONTROL IMPACTS OF SELECTED ALTERNATE FUELS ON EXIST-ING POWER PLANTS.

Stearns-Roger Engineering Co., Denver, CO. E. W. Stenby, W. W. Hoskins, and A. M.

Donaldson, IN: Environmental Problems and Solutions: Greenhouse Effect, Acid Rain, Pollution. Hemi-sphere Publishing Corporation, New York. 1990. p 207-231. 10 fig, 20 ref.

Descriptors: \*Emissions control, \*Energy sources, \*Environmental protection, \*Fuel, \*Future planing, \*Powerplants, Economic aspects, Environmental policy, Hydrocarbons, Natural gas, Peat, Resources management.

Many existing utility boilers were designed to burn oil or natural gases as their primary fuel. Legislative pressures and the increasing cost of oil and natural gas, however, have forced the utility industry to consider alternates to meet the future fuel provisional of these boilers. A number of new requirements of these boilers. A number of new energy technologies and synthetic fuels have been developed in the past few years, which can be adapted to existing utility boilers. Medium Btu gas is a clean alternate fuel which can be utilized at an existing station with little impact on the boiler, is based totally on coal, an abundant US resource not subject to cutoff by overseas conflict. Waste water systems sources include coal pile rainwater runoff, cooling tower blowdown, process waste water, and raw water treatment waste water. Physical, chemical and biological phases are all needed to clean this water. Favorable economics are only

realized when the retrofit is for a large base loaded realized when the retrofit is for a large base loaded power plant and oil escalation rates are above about 7% percent. In contrast, coal-oil mixture (COM) can be used in both large and small boilers with much less substantial capital investments. However, compared to medium Btu gas, COM will have a greater impact on the boiler and ancillaries. The major impacts of COM firing on the power plant water system are increased demineralizer capacity, and additional makeup water required. In addition, COM can only replace about 40% of the oil burned and therefore can only be an interim solution to reducing oil use. Wood and 40% of the oil burned and therefore can only be an interim solution to reducing oil use. Wood and peat's water content and/or low bulk density would generally preclude hauling over the long distances required to reach many existing boilers. (See also W91-11066) (Brunone-PTT) W91-11078

UTILITY PLANNING MODEL FOR THE STUDY OF AIR POLLUTION REDUCTION, Carnegie-Mellon Univ., Pittsburgh, PA. Center for Energy and Environmental Studies.

N. 19te. In: Environmental Problems and Solutions: Greenhouse Effect, Acid Rain, Pollution. Hemi-sphere Publishing Corporation, New York. 1990. p 251-266. 7 tab, 29 ref. US EPA Assistance Agreement No. CR-808514.

Descriptors: \*Acid rain, \*Air pollution, \*Air pollution control, \*Aquatic organisms, \*Mathematical models, \*Model studies, \*Path of pollutants, \*Suspended solids, \*Utilities, Cost analysis, Economic aspects, Future planning, Sulfuric acid.

The emission of pollutants like SO2, NOx, suspended particulates, from electric utility sources, contributes to acid rain, which is considered harmful to fresh water life and crops. Some proposals for reduction of acid rain require limits to be placed on total air pollution from utilities in re-gions that have collections of plants. At present, most regulations only apply to individual plants, and thus existing models cannot predict the impact of regional emission constraints. The Advanced Simulation Model (AUSM) is an annually Utility Simulation Model (AUSM) is an annually recursive simulation model, which can provide detailed unit-specific or plant-specific results. The AUSM, however, has certain drawbacks which make using the model difficult for the study of long-term and multi-region policy issues. A linear programming model, EPOS, was developed for long-range utility planning under regional emission constraints. The model incorporates air pollution reduction strategies like using low sulfur fuel, least emissions dispatching, and pollution control technology hardware installation and operation. Using this optimization model at regional and/or national level together with the more detailed plant level this optimization model at regional and/or national level together with the more detailed plant level annually recursive model, impacts of regional pollution reduction policies on various social and economic parameters like cost of electricity, pattern of electricity usage, etc. (See also W91-11066) (Author's abstract)

MATHEMATICAL MODELLING FOR SUL-PHUR DIOXIDE REMOVAL FROM STACK GASES IN A FLUIDIZED BED OF ACTIVATED SODIUM CARBONATE.

National Research Centre, Cairo (Egypt). Pilot

H. El Abd. and G. El Diwani.

IN: Environmental Problems and Solutions: Greenhouse Effect, Acid Rain, Pollution. Hemi-sphere Publishing Corporation, New York. 1990. p 267-276. 5 fig. 2 tab, 7 ref.

Descriptors: \*Air pollution control, \*Emissions control, \*Fluidized bed process, \*Mathematical models, \*Model studies, \*Sodium carbonate, \*Sulfur dioxide, Effluents, Kinetics, Model testing, Path of pollutants, Water pollution control

The presence of sulfur oxides in stack gases leads The presence of sulfur oxides in stack gases leads to one of the greatest pollution problems today. Control of sulfur dioxide emissions through absorption by a fluidized bed of activated carbonate proved to be not only a feasible process but also to have many advantages over other known processes. A mathematical model describing the overall kinetics of the process was developed, with kinetic parameters evaluated at different reaction temperatures based on integral fluidized bed reactor data. The operating conditions of the experiment were adjusted to simulate the actual conditions found in stack effluents. Therefore, data obtained can be used with a good degree of accuracy, in the design of fluidized bed reactors, for stack gas treatment under similar flow behavior. A high degree of sulfurization (over 95%) is achieved. (See also W91-11080) W91-11080

The exponential increase of crude oil sea and land The exponential increase of crude oil sea and land transport over the last twenty years is the result of an economic expansion and industrial growth on a global scale, especially of the developed and developing countries. The significant threat to the ocean, coastal and estuarine ecosystem stability and ecological diversity because of the oil spills and slicks is a major problem. Oil spills in the marine environment may have reached up to six million metric tons, with about 44% of oil spills resulting from land sources and refineries, 35% ship generated, 10% from natural seepage, and 10% from atmospheric fallout. No single solution exists. The Mediterranean, Caribbean, Baltic, and North Seas and the Arctic region face different oil exists. The mediterranean, Caribocan, battic, and North Seas and the Arctic region face different oil spill and oil pollution problems. Accordingly, a many-sided institutional approach and regional marine pollution control planning, management and agencies are needed to achieve the most effective oil spill prevention. Proper oil transport technicel coordination and management is aimed at energy conservation, which is an excellent environmental quality and protection methodology and planning strategy. AGRICHEMICALS AND GROUNDWATER PROTECTION: RESOURCES AND STRATE-GIES FOR STATE AND LOCAL MANAGE-

MENT.
Proceedings of a Conference held October 24-25, 1988, St. Paul, Minnesota. Freshwater Foundation, Navarre, Minnesota. 1989. 416p.

Descriptors: \*Agricultural chemicals, \*Conferences, \*Groundwater quality, \*Nonpoint pollution sources, \*Path of pollutants, \*Water pollution consources, \*Path of pollutants, \*Water pollution con-trol, \*Water quality management, Agricultural practices, Education, Groundwater pollution, In-formation transfer, Pesticides.

This conference focusing on agrichemicals and groundwater, brought together people from 26 states and Canada. Because fertilizer use has quadrupled between the years 1960-1980 and pesticide use has tripled since 1964, it poses a hazard to groundwater, the source of drinking water for nearly half of the United States and for 97% of its rural population. To date, at least 17 pesticides have been found in groundwater in 23 states, and nitrates have been found in 20% of wells tested throughout the country. The conference highlightintrates have ocen found in 20% of wells teach throughout the country. The conference highlight-ed and analyzed usable, practical information re-sources and model programs presently in place and available to assist states, local entities, and farmers available to assist states, local entities, and armiers in balancing agrichemical use and groundwater protection more effectively. The Geological Survey, Department of Agriculture, Environmental Protection Agency, individual states, local entities, industry, and non-profit organizations described initiatives in information systems, funding, sweets diseased education and training. COMMUNICATING WITH FARMERS: PRO-VIDING USEFUL AND RELIABLE SOURCES OF INFORMATION.

C. K. Constant.

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 37-54, 6 fig, 2 tab, 6 ref.

Descriptors: \*Agricultural chemicals, \*Agricultural practices, \*Groundwater quality, \*Information transfer, \*Nonpoint pollution sources, \*Surveys, \*Water pollution control, Decision making, Farm management, Fertilizers, Groundwater pollution, Pesticides, Tillage, Water quality control.

A survey was conducted of farm operators in Iowa in 1987 to determine: (1) the present pattern of use of sources of information for those crop production operations most related to agricultural chemical use; and (2) the perceived reliability of these information sources. These sources represented mass media, government agencies, personal or peer experience, non-norfic to granizations, and private mass media, government agencies, personal or peer experience, non-profit organizations, and private sector entities. Three aspects of crop production were examined: tillage practices, fertilizer application, and pesticide application. Questionnaires were sent to 360 farmers and 89 valid responses were received. For tillage practices, 94% of the respondents considered their own experience as the spondents considered their own experience as the primary source. Fertilizer application information indicated that although many cited their own experience, local sales dealers were used by 60% and preferred by nearly 25%. Additional sources, in-cluding crop consultants, Extension Service, and farm publications were used by more than 25%. Of

these, consultants and Extension Service were pre-ferred by over 10%. Preferred information sources ferred by over 10%. Preferred information sources for pesticides indicated a need to augment personal experience with outside sources. Sales dealers were cited as most preferred by 30%, with personal experience a close second at 28%. Other preferred sources were manufacturer representatives and crop consultants. Reliability estimates were based to a combination of the presentation of the presentation of the presentation. on a combination of the perception of the source's bias and the validity of the information it disseminates. The Soil Conservation Service was considered to be most reliable followed by the Extension Service. Chemical company representatives were considered to be the least reliable. Therefore, it appears that no one source provides trusted, unbiased, applied, personalized, and knowledgeable advice to farmers to persuade them to reduce their chemical inputs. To be effective, public programs dealing with groundwater protection will have to motivate farmers to seek out new knowledge. advice from new and existing sources that they trust and find useful. (See also W91-11162) (Rubin-

EMERGING ISSUES AT THE INTERSECTION OF AGRICULTURAL AND ENVIRONMENTAL POLICY.

G. Torres.
IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 55-58.

Descriptors: \*Agricultural chemicals, \*Ground-water quality, \*Information transfer, \*Nonpoint pollution sources, \*Surveys, \*Water pollution con-trol, Agricultural practices, Attitudes, Decision making, Farm management, Groundwater pollu-tion, Herbicides, Pesticides, Water quality control.

Farmers were interviewed in five watershed areas in different parts of the country to ascertain their attitudes about groundwater contamination and possible solutions. An additional goal was deter-mine sources of farmers' information and the effect on beliefs and attitudes. The farmers' preference as a source for pesticide and herbicide information was: Cooperative Extension Service > chemical manufacturers and dealers > Soil Conservation Service. Nearly 90% of the farmers believed that Service. Nearly 90% of the farmers believed that free technical advice would help reduce their dependence on herbicides and pesticides. More than 75% would be willing to rotate crops, so long as their commodity base could be protected. A substantial minority considered groundwater to be their property to use and treat as they see fit. This attitude could generate resistance to future legislation. WELLHEAD PROTECTION-INFORMATION AND RESOURCES. S. P. Roy. IN: Agrichemicals and Groundwater Protection:

Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 135-143, 1 fig, 2 tab.

Descriptors: \*Groundwater quality, \*Nonpoint pollution sources, \*Water quality control, \*Wells, Agricultural chemicals, Information exchange, Information transfer, Management planning, Training, Water quality, Wellhead protection.

Many states are moving forward with innovative legislation to address various aspects of the agri-

chemical/groundwater issue. The Wellhead Protection program provides a framework for state agencies to consider agricultural impacts on groundwater quality and to develop and implement groundwater protection programs. As a resource to assist state and local governments to develop and implement programs to address agrichemicals and groundwater protection, the Environmental Protection Agency (EPA) has Groundwater Representatives in each of its ten regional offices. These individuals and their staffs are available to assist state and local officials in all areas of groundwater protection. (See also W91-11162) (Korn-PTT) W91-11172 W91-11172

CROP DATA MANAGEMENT SYSTEMS, INC. MEETING CALIFORNIA'S PESTICIDE REGULATION CHALLENGE.

R. A. Krause.

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 175-179.

Descriptors: \*Agricultural practices, \*California, \*Computer programs, \*Databases, \*Nonpoint pollution sources, \*Pesticides, \*Water pollution contol, Agricultural chemicals, Compliance, Groundwater contamination, Legislation, Regulations, Water quality.

In response to California's agricultural and environmental regulations and legislation, agrichemical manufacturers, formulators, distributors, retailers, advisors (salespeople), and farmers have developed a need for an efficient method of insuring the proper use of agrichemicals. Crop Data Management Systems, Inc. (CDMS) from Marysville, CA ment systems, inc. (CDMs) from Marysville, CA
has developed a computerized pesticide recommendation writing system called the Advanced
Consultant Service (ACS). ACS provides automatic checking of the proposed pesticide usage against
a Product Label Data Base supplied by the product manufacturers and against the current state and uct manufacturers and against the current state and federal regulations governing the use and recommendation of the product. CDMS has also developed a label referencing system called the Agricultural Pesticide Label Service (APLS) for those states where written pesticide use recommendations are not required. APLS allows rapid searching of the Product Label Data Base for all products that meet sixtem existence APLS will then grief. ucts that meet given criteria. APLS will then print concise information on the particular use of the product requested. APLS also contains the MSDS information for the product in the data base. FUNDING GROUNDWATER PROTECTION PROGRAMS: IOWA'S GROUNDWATER PROTECTION FUND.

Iowa Dept. of Environmental Quality, Des Moines.

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 203-206.

Descriptors: \*Administrative agencies, \*Funding, \*Groundwater resources, \*Local governments, \*Nonpoint pollution sources, \*Water pollution control, Agriculture, Hazardous wastes, Oil industry, Solid wastes, Storage tanks, Underground storage.

The Iowa Groundwater Protection Act, and its associated funding structure, has received a lot of attention in recent years. The Act is based on the 1987 Iowa Groundwater Protection Strategy. The Strategy did not make specific recommenda The low Groundwater Programs might be funded. The low Groundwater Protection Act was originally projected to raise somewhere around 38 milion dollars in revenue in its first five years. In addition, it allocates 17.5 million dollars of the state's oil-overcharge funds to energy related por-tions of the Iowa's program. The actual revenues for the first year were slightly lower than antici-

### Field 5—WATER QUALITY MANAGEMENT AND PROTECTION

## Group 5G-Water Quality Control

pated. However, the revenues have been increasing and are expected to come close to meeting the original projections by this time next year. The Act establishes an Iowa Groundwater Protection Fund, and within the fund five accounts. These accounts include a Solid Waste Account, a Household Hazardous Waste Account, a Storage Tank Management Account, and an Agricultural Management Account. The Act spells out in detail how money is to be generated as well as how it is to be spent. The generated as well as how it is to be spent. The accounts are program specific. That is to say, the accounts are program specific. Intal is only, the money generated in a program area can only be spent on solving the problems associated with that program. In addition, the accounts act as revolving fund accounts and, with the exception of oil over-charge funds, carry-over from year to year. (See also W91-1162) (Korn-PTT)

MINNESOTA CLEAN WATER PARTNERSHIP

Minnesota Pollution Control Agency, Roseville.

Minnesota Poliution Control Agency, Roseville. W. P. Anderson. IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 213-217.

Descriptors: \*Minnesota, \*Nonpoint pollution sources, \*Water quality control, \*Water resources management, Administrative agencies, Cost sharing, Economic aspects, Governmental interrelations, Local governments.

Recent evidence indicates that nonpoint source (NPS) pollutants entering surface and groundwaters in runoff and seepage from land areas affects ers in runon and seepage from and actas ancers most of Minnesota's water resources, and current programs are unable to deal adequately with the problem. In response to this, the Minnesota Legislature enacted the Clean Water Partnership (CWP) in 1987. The purpose of the CWP is to provide interested local units of governments with reinterested tocal units of governments with re-sources to establish water quality projects designed to protect and improve the water quality of lakes, streams, and groundwater affected by NPS pollu-tion. These resources are in the form of 50-50 matching grants, and technical assistance from the Minnesota Pollution Control Agency (MPCA) and other state agencies. It is the sharing of project development and implementation responsibility that characterizes the partnership between state that characterizes the partnership between state agencies and local governments in controlling NPS pollution. The partnership is formulated to provide flexible solutions to unique local problems through a diagnostic study, implementation plan, and an implementation project. However, the CWP is a diagnostic study, implementation pian, and an implementation project. However, the CWP is supported by limited state funds. Grant applications are reviewed by the MPCA and awarded points based on specific criteria. Those water quality projects with the most points would be eligible to receive the grants first. A project coordination team made up of up to thirteen federal and state agencies, the University of Minnesota, and local agencies, the University of Minnesota, and local government representatives will assist the MPCA in project evaluation and selection as well as pro-vide coordinative and technical support to the projects. The Massachusetts Department of Environmental Quality Engineering, Division of Water Supply

conducts an active program to protect the quality of public supply wells and groundwater. A key element of this program is the control of land uses which may adversely affect groundwater quality. The State's approach emphasizes protection of the recharge area of public supply wells, achieved through definition and delineation of protection zones around the well. By applying the same prozones around the well. By applying the same pro-tection area, definition to programs of more than one state agency, and at both the local and state level, a synergy has been achieved that has permit-ted much to be done even with limited staff and funding. Goundwater contaminant monitoring programs throughout the United States are revealing wide-spread groundwater contamination by agricultural and industrial chemicals at concentrations of environmental and public health concern. The federal government's reticence to establish a national groundwater resource protection program with groundwater testure protection program with numerical enforcement standards, based on health effects toxicology data has, in many instances, forced the development of state-led programs to address pressing local needs. The Wisconsin De-partment of Health and Social Services has been active in the development of Wisconsin's ground-water standards development or corrent. Isoconsactive in the development of wisconsin s ground-water standards development program. Informa-tion regarding pesticide environmental fate and toxicology issue are needed if the states are to successfully implement the U. S. Environmental Protection Agency (EPA) agrichemical strategy. The Wisconsin numerical standards program was developed through involvement in standards set-ting and performing risk assessments in communi-ties with contaminated sole source aquifers. Imple-mentation of the numerical standards based groundwater law has proceeded successfully since the passage of the act in 1984. State agency implementation of groundwater standards has resulted in the alteration of activities and practices which could result in contamination of groundwater above an enforcement standard. Agricultural prac-tices have been altered to take into account the propensity of certain agrichemicals to enter groundwater after normal agricultural use. Parties responsible for contaminating groundwater have been prosecuted and have been forced to pay damages resulting from their acts. (See also W91-11162) (Korn-PTT) W91-11183

### RURAL CLEAN WATER PROGRAM.

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minneta. 1989. p 257-258

Descriptors: \*Nonpoint source pollution, \*Water pollution controls, \*Rural areas, Evaluation, Cost sharing, Water quality, Agriculture, Conservation, Management planning.

The Experimental Rural Clean Water Program (RCWP) was an experimental program developed to evaluate the effectiveness of applied best man-agement practices (BMP's) in controlling agriculture nonpoint source pollution for improved water quality. Twenty-two projects were selected and funded for implementation based on extensive plans of work desribing watersheds with seriuous plans of work destribing watersheds with serulous agricultural nonpoint source pollution problems, documenting water use impariments and outlining best management practices to be applied to help reduce the problems and improve water quality. Full scale, multilevel water quality monitoring programs were implemented to determine the effects of applied conservation on water quality in surface of applied conservation on water quality in surface and groundwater resources in these project areas. The RCWP uses the concept of long-term contracts as the basis for cost sharing participants. Long-term contracts require a participant to carry out elements of a conservation plan over a specified number of years. Cost share funds are available to help install selected BMP's on critical acres. The conservation plan became the cornerstone of the program. It identified those conservation practices needed to reduce or eliminate resource prob-lems that would lead to water quality degradation or water use impairment. RCWP was the first program in which Soil Conservation Service (SCS) developed water quality conservation service (SCS) developed water quality conservation plans aimed directly at reducing agricultural nonpoint source pollution. ## Water Quality Control—Group 5G

vention, Costs, Education, Regulations, State jurisdiction

By 1986 the Northwest Kansas Groundwater Management District No. 4 board decided it wanted to address the issue of abandoned wells as ground-water contamination threats. The district's man-agement program now had to deal with traditional water quantity issues as well as water quality issues. The district board decided that its approach to water quality would be committed primarily protection and prevention issues. The organizati protection and prevention issues. The organization of the management program requires that a problem be identified; then a program is designed to address the problem. If the program needs implementation or enforcement authority, a policy, resolution or regulation is then passed. Since the management program is required to be reviewed and either modified or re-adopted annually, this proc-ess remains timely and responsive for the district's needs as these needs change and/or evolve. Each needs as these needs change and/or evolve. Each management program goes through state adoption and local public hearing prior to implementation. Of all the wells located and initiated into the system, approximately 80% have responded to the district's initial notification letter. Overall, the abandoned well program has addressed many wells which would not have otherwise been dealt with. (See also W91-11162) (Korn-PTT) W91-11188

CENTRAL PLATTE NATURAL RESOURCES DISTRICT'S GROUNDWATER MANAGE-MENT PROGRAM.
Central Platte Natural Resources District, Grand

The Central Platte Natural Resources District (CPNRD) covers over 2 million acres in south central Nebraska. In 1973, over 500 irrigation and domestic wells were sampled revealing high groundwater nitrate concentrations. Additional studies were conducted to determine the studies were conducted to determine the source of the nitrate contamination. It was determined that most of the nitrates in the groundwater could be directly attributed to excess commercial nitrogen fertilizers being applied to the fields. In 1979, the CPNRD initiated a project to determine ways of reducing nitrogen leaching and possibly cleaning up the already polluted groundwater by establishing test fields where district staff worked with the farmers on nitrogen applications, irrigation scheduling, and harvest. However, re-sampling in 1983 revealed that nitrate levels had increased substantially. The CPNRD has since established a Groundwater Management Plan which is based on past research carried out by the district and numerpast research carried out by the district and numer-ous state and federal agencies. It is designed not to reduce crop yields. By balancing the system and only applying the nitrogen needed, yields can be maintained and groundwater pollution reduced. The adopted program established 'Phases' based on the seriousness of the groundwater nitrate prob-lem. The more serious the problem the higher the phase. In addition, operators are required to attend education or certification classes. (See also W91-11162) (Korn-PTT) W91-11190

## RETURNABLE PESTICIDE CONTAINERS: MAINE'S DEPOSIT AND COLLECTION MAINE'S SYSTEM.

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 307-310.

cides, \*Regulations, \*Solid waste disposal, \*Waste disposal, \*Water pollution control, Administrative agencies, Pesticide containers, State jurisdiction.

In 1983 the state of Maine's Board of Pesticides Control (BPC) prepared legislation to require triple rinsing and return of restricted use pesticide containers made of glass, metal or plastic. The four main components of the new law are as follows: (1) all limited and restricted use pesticides contain-(1) all limited and restricted use pesticides containers, excluding those made of cardboard, fiberboard or paper, must be triple rinsed according to regulations promulgated by the BPC; (2) dealers must charge a deposit at the time of sale sufficient to ensure return of the container (by regulations, the BPC set the deposit at five dollars for anything smaller than 10 gallon drums and ten dollars for 30 gallon and larger drums); (3) all containers covered under this act must bear an alpha numeric sticker to identify the purchaser and dealer (normally this would be attached by the dealer and recorded at the time of sale); and (4) the deposit would not be would be attached by the dealer and recorded at the time of sale); and (4) the deposit would not be refunded until the container had been triple rinsed and returned to the seller or an alternate designatand returned to the sense of an atternate designation of the season collections are conducted at nineteen locations throughout the state. The return process works best when the containers can be buried in the community where containers can be buried in the community where they are inspected. Unfortunately, this only hap-pens at eight of the 19 sites so the BPC and the dealers have had to make special arrangements to get the containers transported to a commercial landfill in the center of the state. #### PESTICIDE RINSEATE MANAGEMENT PLAN. T. Ambroz.

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 343-351.

Descriptors: \*Hazardous waste disposal, \*Minnesota, \*Nonpoint pollution sources, \*Pesticides, \*Wash water, \*Waste management, \*Wastewater disposal, \*Water pollution control, Contamination, Design criteria, Economic aspects, Management planning, Monitoring, Pesticides spraying, Rainfall, Regulations, Storage tanks, Underground storage.

The Minnesota Agricultural Aircraft Association with the help of the Minnesota Technical Assistance Program (MN TAP) has developed a Pesticide Rinseate Management Plan. The project goals included the collection of pesticide rinseate and equipment washwater, the minimization of water waster and the verse of investical and washer the project of the state of the project of the state runoff, and the reuse of rinseate and washwater. The basic system consisted of a concrete slab with curbs constructed on a gravel base with a slope away from the slab. Several factors were considered in the area of system design and system man-agement. The first factor included the use of plasitc liners and/or underground monitoring systems. It was decided to forego any underground monitoring system, but cracks in the concrete must be toring system, but cracks in the concrete must be repaired promptly. A second factor involved the control of rainwater discharge. Several design and management techniques were adopted to allow management decisions based on operational differ-ences and economic considerations. Another factor

involved in the design was the management of sediment accumulation in the sump. To avoid cross contamination, sediment must be cleaned out when switching from one target crop pesticide to another. A fourth factor that was considered inother. A fourth factor that was considered involved the management of rinseate and washwater which would be collected in separate above-ground storage tanks. The final factor involved the potential classification of the sump as an underground storage tank. This issue was settled when the Minnesota Pollution Control Agency (MN PCA) declared that sumps are classified as underground storage tanks under federal regulations. ## PROFESSIONALISM IN AGRICULTURE: SEEKING A TRAINING STANDARD.

J. A. Ladlie. IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 365-370.

Descriptors: \*Agricultural chemicals, \*Education, \*Fertilizer management, \*Information exchange, \*Information transfer, \*Nonpoint pollution sources, \*Training, Certification, Professional per-sonnel.

There is a growing realization that, as suppliers of information to growers, individuals in the agrichemical industry need to be highly qualified. The information provided to farmers must be accurate, useful, and timely. In order to respond to the demand for information, the agrichemical dealers and manufacturers' representatives need to reach a high level of knowledge and expertise. The Nehigh level of knowledge and expertise. The Ne-braska Certified Crop Production Advisor (NCCPA) Foundation, in collaboration with the Agri-Growth Company, have developed a chal-lenging program of testing and certification for agrichemical professionals. Agri-Growth provides the professional training development services and the NCCPA Foundation provides review and sponsorship. The instruction is presented in two one-week sessions, each of which culminates in a test Each of the tests must be passed with a 75%. test. Each of the tests must be passed with a 75% minimum passing score in order for the trainee to become a Certified Crop Production Advisor. Due to the success and increasing interest in the pro-gram from other states, the NCCPA has decided to move in the direction of a national program of certification. ## MARYLAND'S TRAIN-THE-TRAINER PRO-GRAM HOUSEHOLD HAZARDOUS WASTE.

M. L. Sowell.

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 377-383.

Descriptors: \*Drinking water, \*Education, \*Hazardous waste disposal, \*Information transfer, \*Maryland, \*Nonpoint pollution sources, \*Water pollution prevention, Domestic wastes, Groundwater management, Groundwater pollution, Training, Water resources management, Workshops.

Two counties in Maryland were selected as pilot test sites for a drinking water outreach program. The objective of the program would be to increase individual household knowledge about drinking water and how individuals' practices can affect the quality of drinking water. The Community Resource Development Agents in both counties developed a strategy for maximizing audience outreach by conducting a Train-The-Trainer Workshop. Those people interested in becoming a trainer would have to agree to train others in the community. Participants in the workshop received a number of fact sheets pertaining to household products and the disposal of these products, and information of water quality and water resources. A slide presentation was also shown to the trainers and included information on the disposal of hazardous waters. A referral and information and information on the disposal of hazardous waters. ardous waste. A referral and information fact sheet accompanied each slide. Once the training was over, the participants were ready to go out to conduct similar workshops in the communalso W91-11162) (Korn-PTT) W91-11200

## FARM BUREAU'S GROUNDWATER AND EN-VIRONMENTAL QUALITY SELF-HELP CHECKLIST FOR FARMSTEADS AND FARM

I Porterfield

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 387-392, 1 fig.

Descriptors: \*Agricultural chemicals, \*Education, Nonpoint pollution sources, Water pollution prevention, Drinking water, Environmental protection, Farm management, Farms, Groundwater pollution, Regulations, Surveys, Training, Water qual-

Voting delegates at the American Farm Bureau Federation's national annual meeting in 1986 rec-ommended that the Farm Bureau create a special ominence that the Farm bureau create a special environmental pollution task force in response to growing concern about the impact of agricultural chemicals on drinking water supplies. This special study committee noted the site specific nature of groundwater, soil types, climate and natural pollut-ants. They also recognized the need to improve ants. They are recognized the need to improve nutrient management and minimize nitrogen losses to the environment. The task force concluded that a questionnaire/checklist type program should be developed to highlight safe storage and handling of agricultural chemicals, mixing, and loading loca-tions and techniques. The development of the checklist took about one year. Each state Farm Bureau was provided with a set of camera-ready slicks which could be modified to reflect state laws and farming practices. Information on the slicks and other related services are part of a package supplied to each state Farm Bureau. The Farm Bureau's Self-Help Checklist is really a tool to raise questions and prompt farmers to search out answers and best management practices from extension and health officials. The state of Florida has developed an in-service training program entitled 'Pesticide Usage and Its Potential Impact on Surface and Groundwater Quality.' The program is conducted annually by the Florida Cooperative Extension System (CES). A multidisciplinary team of instructors are used to provide excellent resource expertise and materials provide excellent resource expertise and materials that the county extension agents can draw upon as they develop materials and programs for county use. The content of the training course consists of four principle segments which make up the core materials offered each time and two or three segments which vary depending on availability of resource persons and current issues regarding pesticide use in the state. The four principle segments include the following (1) geochytekelogy and the include the following: (1) geohydrology and the water cycle, (2) sources of contamination, (3) physical, chemical, and biological processes that con-trol pesticide fate in the environment, and (4) management practices to rescue or prevent water quality impairment. A concerted effort is made to assure that the audiences make the connection between the water resources potentially being impacted, the processes that control chemical fate nd transport in the environment, and management alternatives that can reduce or prevent these im-pacts. A manual is provided for each training session that consists of Extension fact sheets, circulars, research articles, and other available relevant materials that contribute to the understanding of the subject. In addition to the above materials, microcomputer software has been developed as a teaching tool to reinforce understanding of pesticide fate in soils. (See also W91-11162) (Korn-PTT) W91-11202

## STRATEGIES FOR NONPROFIT ORGANIZA-TIONS FOR PREVENTING AGRICHEMICAL CONTAMINATION OF GROUND WATER.

Center for Rural Affairs, Hartington, NE. Sustainable Agriculture Project.

R. Krupicka. In: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 407-410.

Descriptors: \*Agricultural chemicals, \*Nonpoint pollution sources, \*Organizations, \*Public participation, \*Water pollution prevention, Administrative agencies, Environmental protection, Farming, Water pollution, Water re-

More innovative and creative strategies are needed to address the many complex environmental, social, and economic problems associated with agricultural chemicals and groundwater quality issues. Non-profit organizations can play a role in addressing these problems by promoting change in the existing system and by innovative and creative approaches to problem solving. In addition, non-profit organizations can hold public institutions to their responsibility of seeking and implementing solutions rather than allowing them to avoid or place the responsibility elsewhere. The main public place the responsibility eisewhere. The main public institution that has provided information on various farming practices has been the land grant research and extension system. The Center for Rural Affairs, a private non-profit organization, has provoked public thought about social, economic, and environmental issues affecting rural America by using a wide range of strategies. One rather suc-cessful strategy that a number of grassroots organi-zations have used is to embarrass the land grant system into examining more sustainable farming practices. A second strategy is that of trying to develop a new leadership that is concerned about groundwater quality and related environmental, social, and economic issues. A third strategy is to develop a system of support for those individuals within the system that recognize the need for reforming farming practices but are in a minority and meet substantial institutional resistance. A and meet substantial institutional resistance. A fourth strategy is to know about and understand the decision-making processes used by the land grant system or other relevant public institution. The fifth strategy is to play the role of 'watchdog' by monitoring how the implementation process is being carried out. (See also W91-11162) (Korn-W91-11204

## IN THE LAND OF THE GIANTS: GRASS-ROOTS ORGANIZING IN CALIFORNIA'S CENTRAL VALLEY.

NATURE OF SUSPENDED SOLIDS AND IRS1A-LISSI DATA: A CASE STUDY OF TAWA RESERVOIR (NARMADA BASIN), Jawaharlal Nehru Univ, New Delhi (India). School of Environmental Sciences. V. K. Choubey, and V. Subramanian. Remote Sensing of the Environment RSEEA7, Vol. 34, No. 3, p 207-215, December 1990. 4 fig, 3 tab. 16 ref.

Descriptors: \*Remote sensing, \*Suspended solids, \*Tawa Reservoir, \*Water quality, Data acquisition, Data interpretation, Evaluation, India, Indian Remote Sensing Satellite-1A, Linear Imaging Self-Scanning, Mineralogy, Narmada River Basin, Particle size, Satellite technology.

Spectral digital data from the Indian Remote Sensing Satellite-IA Linear Imaging Self-Scanning (IRSIA-LISSI) sensor were analyzed to determine the feasibility of quantifying the concentration of suspended solids in the water by this sensor. For this purpose, a small tributary (Tawa) of a major river basin (Narmada Basin) in central India was river basin (Narmada Basin) in central india was studied for ground truth evaluation of the IRSIA-LISSI digital data. Tawa Reservoir water samples were collected on 20 October 1988, concurrent with IRSIA overpass. The samples were analyzed to determine the concentration of total suspended to determine the concentration of total suspended matter, grain size, and mineralogy. The results indicate that, in the concentration range between 10 mg/L and 50 mg/L, a positive functional relationship exists between the concentration of suspended solids and the visible wavelength bands 1, 2, and 3 (0.45-0.68 micrometers). Mineralogy and grain size are the main factors that influence the reflected radiance at a lower concentration level. grain size are the main factors that influence the reflected radiance at a lower concentration level (10-50 mg/L) of suspended solids. It can be concluded that as the concentration of suspended solids in the 10-50 mg/L range increases, the spectral response increases. IRISIA-LISSI data provide a good foundation for further development of remote sensing as a practical tool in the estimation of suspended solids. (Author's abstract) W91-11221

BUBBLELESS AERATION.
Minnesota Univ., Minneapolis. Dept. of Civil and
Mineral Engineering.

M. J. Semmens.
Water Engineering and Management WENMD2,
Vol. 138, No. 4, p 18-19, April 1991. 1 fig.

Descriptors: \*Aeration, \*Lake restoration, \*Membrane processes, \*Oxygenation, \*Water quality control, \*Water treatment, Diffusion, Field tests, Gases, Lake St Paul, Mathematical equations, Minnesota, Performance evaluation.

A hollow-fiber membrane aerator for the oxygenation of water has been developed and tested. The aerator houses a bundle of sealed, hollow, gaspermeable fibers that are filled with pure oxygen under pressure. The water to be aerated is pumped over the outside of the fibers. The device can aerate water without forming bubbles. The oxygen diffuses across the porous fiber walls and dissolves directly into the water that flows over the outer surface of the membrane. The highly oxygen-persurface of the membrane. The highly oxygen-per-meable membrane transfers oxygen to the water so meable membrane transfers oxygen to the water so quickly that transfer takes place as if the membrane were not present. In essence, the fibers act as elongated, stationary bubbles of oxygen. The hollow fibers are made from microporous polypropylene membrane, and measure approximately 200-400 micrometers in diameter. The small size of the fibers means that a very large surface area of membrane can be installed in a small aerator. The basic equation for oxygen transfer is dC/dt = K sub La (C\*-C), where K sub La is the overall oxygen transfer coefficient, C\* is saturation concentration in the dissolved oxygen concentration in equilibrium with the air or oxygen), and C is the equilibrium with the air or oxygen), and C is the actual concentration of dissolve oxygen in the actual concentration of dissolve oxygen in the water. Oxygen transfer is accomplished by making K sub La and C\* large. Field tests were conducted with a 1000-fiber module in Lake St. Paul, Minnesota, over a period of 5 mo. The data show a trend of decreased transfer over the test period, but this is attributable to temperature changes. The memorated brane consistently performed better than expected in the field, with no evidence of membrane fouling. (Rochester-PTT)

ANALYTICAL MODELING OF AQUIFER DE-CONTAMINATION BY PUMPING WHEN TRANSPORT IS AFFECTED BY RATE-LIMIT-ED SORPTION.

ED SORPTION.
Air Force Inst. of Tech., Wright-Patterson AFB, OH. School of Civil Engineering.
M. N. Goltz, and M. E. Oxley.
Water Resources Research WRERAQ, Vol. 27, No. 4, p 547-556, April 1991. 6 fig, 34 ref.

Descriptors: \*Aquifer restoration, \*Cleanup operations, \*Mathematical models, \*Pump wells, \*Water pollution treatment, Aquifers, Comparison studies, Data interpretation, Groundwater pollution, Laplace equation, Model studies, Numerical analysis, Solute transport, Sorption.

Aquifer cleanup efforts at contaminated sites frequently involve the operation of a system of extraction wells. Contaminant load discharged by extraction wells typically declines with time, asymptotically approaching a residual level. Such behavior could be due to rate-limited desorption of an organic contaminant from aquifer solids. An analytical model was developed that accounts for rate-limited desorption of an organic solute during cleanup of a contaminated site. Model equations are presented that describe transport of a sorbing contaminant in a converging radial flow field, with desorption described by (1) equilibrium, (2) first order rate, and (3) Fickian diffusion expressions. The model equations are solved in the Laplace domain and numerically inverted to simulate contaminant concentrations at an extraction well. A Laplace domain solution for the total contaminant mass remaining in the aquifer also is derived. Ratemass remaining in the aquifer also is derived. Rate-limited sorption can have a significant impact on aquifer remediation. Approximate equivalence among the various rate-limited models also is demonstrated. (Author's abstract) W91-11235

OPTIMAL DATA ACQUISITION STRATEGY FOR THE DEVELOPMENT OF A TRANSPORT MODEL FOR GROUNDWATER REMEDI-

ATION.

The reliability of groundwater management algorithms is limited in large part by the uncertainty present in the model parameters. Because the field parameter measurement costs and remediation costs must be supplied by the same financial source; the classical optimization procedure does not minimize the real total remediation investment. An algorithm was developed that is capable of finding the total minimum for the sum of both the finding the total minimum for the sum of both the measurement and the pumping costs. A chance-constrained technique is used to cast the optimization problem in stochastic form, relating the concentration covariance matrix to the log-transmissivity covariance matrix by means of the transport equations and a first-order approximation for uncertainty. The simulation model solves the steady state flow equations on finite element triangular mesh and the transport equations using the backward method of characteristics. The resulting nonlinearly constrained optimization problem is solved using the quasi-linearity algorithm; this algorithm is designed to find a good initial point for the local minimum search when the feasible domain is not convex. Hydraulic filling of certain land areas in the Soviet Union can have a beneficial environmental effect.

One application is in the polder reclamation of shoals of large water power reservoirs where the shoals constitute a 'no-man's land' of little economic value. Use of hydraulic mining methods in ex-traction of minerals is inexpensive, but it leads to traction of funerais is inexpensive, our it reads to the creation of tailings dumps. Care must be taken in building tailings dumps not to release waste into the local water and air. The new environmental protection technology of forming hydraulic dumps includes: an evaluation of the state of sloping structures and internal zones of hydraulic-fill masses tures and internal zones of hydraulic-full masses with the use of routine geomechanical monitoring and special engineering-geological regionalization; geomechanical substantiation of the designs of the slopes of embankments and measures on forcing consolidation of water-saturated soil; creation of components of a designee autem, within stores. components of a drainage system within various zones of hydraulic dumps to increase their capaczones of nydraulic dumps to increase their capacity, accelerating the turnover of water and providing the possibility of subsequent use of the hydraulic-fill territories; and dust suppression by hydraulic placement of a loam blanket on the dust-producing surface. At two dumps of the Lebedinsk Mining and Concentration Integrated Plant and KMA-Ore Integrated Plant, a total of 938 ha of previsions of the processing the proces fertile chernozem land, including 328 ha of previ-ously unsuitable lands (ravine slopes), were revege-tated and returned to agriculture. Soil vapor stripping (vacuum extraction) has become an important tool in the remediation of hazardous waste sites contaminated with volatile organic compounds (VOCs) in the vadose zone. A mathematical model for in-situ soil vapor stripping was developed and used to examine the effects of a was developed and used to examine the effects of a spatially variable pneumatic permeability tensor on the rate of cleanup of a site contaminated with VOCs. A study was made of the effects of lens-shaped domains of low permeability on the shapes of the streamlines of soil gas in the vicinity of a vapor stripping horizontal lateral slotted pipe and

## Field 5—WATER QUALITY MANAGEMENT AND PROTECTION

## **Group 5G—Water Quality Control**

on the rate of cleanup of the soil in the domain of influence of this pipe. The effects of spatial variation in the soil moisture were also examined. Runs were made with low-permeability clay lenses placed at various locations in the domain of interest. The model permits one to carry out a sensitivity analysis of the effects of heterogeneity in the permeability, and to develop strategies for minimizing the damaging effects of domains of low permeability. Vapor stripping of rather wet soil is likely to be a very slow process. In such situations, efforts to reduce surface recharge, to draw down the level of the water table by pumping, and to allow adequate time for soil drainage after the water table had been drawn down may be necessary in order to achieve acceptable containment removal rates by soil vapor stripping. (See also removal rates by soil vapor stripping. (See W90-11832 and W91-01756) (VerNooy-PTT)

DENITRIFICATION IN LABORATORY SAND COLUMNS: CARBON REGIME, GAS ACCUMULATION AND HYDRAULIC PROPERTIES. Ben-Gurion Univ. of the Negev, Sde Boker (Israel). Jacob Blaustein Inst. for Desert Research. M. I. M. Soares, C. Braester, S. Belkin, and A.

Abeliovich. Water Research WATRAG, Vol. 25, No. 3, p 325-332, March 1991. 6 fig, 3 tab, 16 ref.

Descriptors: \*Aquifers, \*Biological treatment, \*Denitrification, \*In situ treatment, \*Restoration, \*Water pollution, Anaerobic bacteria, Biomass, Clogging, Hydraulic conductivity, Nitrates, Per-meability, Porosity, Sand filters.

The biological approach to restoration of nitrate polluted aquifers relies on the capacity of faculta-tive anaerobic bacteria, in the absence of oxygen, to utilize nitrate as a terminal electron accepto their respiratory process via a pathway known as denitrification. In situ denitrification treatment is denitrification. In situ denitrification treatment is achieved by injecting an organic carbon source into the aquifer. Although build-up of biomass and a marked decrease in permeability are observed, removal of accumulated gas brings significant increases in permeability. Microbiological denitrification in a sandy matrix was studied by means of laboratory sand columns operated at continuous and pulse feed regimes. Gas production resulting from the biological activity played a major role in modifying the hydraulic properties of the column, leading to decreases in hydraulic conductivity and porosity, higher water velocities through the porosity, higher water velocities through the column, higher dispersion and anomalities in the head difference to flow rates ratios. All of these head difference to flow rates ratios. All of these effects were more pronounced when formate, the carbon source used, was supplied continuously: microbial activity and gas production were concentrated at the top of the column, leading to almost complete clogging. When the formate was supplied in pulses, activity and gas production dispersed, leading to relative uniformity in the physical parameters measured and a homogeneous physical parameters measured and a homogeneous physical parameters measured and a homogeneous appearance of the column. The results suggest that in a future in situ aquifer denitrification plant, pulse application of the carbon source is preferable to a continuous supply regime. (Doyle-PTT) W91-11330

APPLICATION OF SUPPORTED LIQUID MEMBRANES FOR REMOVAL OF URANIUM FROM GROUNDWATER. Argonne National Lab., IL. Chemistry Div. R. Chiarizia, E. P. Horwitz, P. G. Rickert, and K.

M. Hodgson. Separation Science and Technology SSTEDS, Vol. 25, No. 13/15, p 1571-1586, 1990. 8 fig, 4 tab,

Descriptors: \*Cleanup operations, \*Groundwater pollution, \*Membrane processes, \*Separation tech-

niques, \*Uranium, \*Water pollution treatment, Chemical recovery, Hanford, Polymers.

The separation of uranium from Hanford site groundwater was studied by hollow-fiber supported liquid membranes (SLM). The carrier bis(2,4,4trimethylpentyl)phosphinic acid, H(DTMPeP), contained in the commercial extractant Cyanex 272, was used as the membrane carrier because of its selectivity for U over calcium and magnesium. The water soluble complexing agent, 1-hydrox-yethane-1,1-diphosphonic acid (HEDPA) was used as the stripping agent. Polypropylene hollow-fibers and n-dodecane were used as polymeric support and diluent, respectively, Laboratory scale hollowand diluent, respectively. Laboratory scale noilow-fiber modules were employed in a recycling mode, using as feed synthetic groundwater at pH 2, to confirm the capability of the proposed SLM system to separate and concentrate U(VI) in the strip solution. Information was obtained on the strip solution. Information was obtained on the U(VI) concentration factor and on the long-term performance of the SLMs. Encouraging results were obtained both with a conventional module and with a module containing a carrier solution reservoir. Industrial scale modules were used at Hanford to test the SLM separation of U(VI) from real contaminated groundwater. The uranium con-centration was reduced from approximately 3,500 ppb to about 1 ppb in a few hours. (Author's abstract) W91-11370

Descriptors: \*Groundwater pollution, \*In situ treatment, \*Path of pollutants, \*Water pollution treatment, Analytical methods, Biodegradation, Cleanup operations, Gas chromatography, Industrial wastes, Mass spectroscopy, Model studies, Organic compounds, Precipitation, Sulfates.

For more than two decades, a chemical processing waste liquor containing substantial concentrations of organic species and ammonium sulfate (up to 38,000 mg/L sulfate), was discharged into shallow trenches adjacent to a manufacturing plant. The waste materials have reacted and migrated to the subsurface domain; a multi-phase plume has resulted. Source material was assayed for surface tension, viscosity, and density, followed by mass spectroscopic analysis. GC/MS results indicated that a substantial part of the waste was comprised of short chain volatile fatty acids. The surface tension of contaminated groundwater correlated well with organic carbon content. Source material clearly had considerable surfactant properties associated with it, with a surface tension 60% lower than pure water. Local soils were also characterized ( 90% sand, 4% silt, and 6% clay) since migration of sain, 40 ain, and o've clays since ingration or the plume depends of both the physical properties of the waste and of the solid support matrices. A laminar jet model was developed to explain transport behavior. Process design considerations tend to favor an in situ treatment process. It appears that sulfate removal by precipitation as a prelimi-nary step can be followed by groundwater recov-ery and above ground microbial treatment. (Doyleery an W91-11380

DANUBE RIVER BASIN: NEGOTIATING SET-TLEMENTS TO TRANSBOUNDARY ENVI-RONMENTAL ISSUES. International Inst. for Applied Systems Analysis, Laxenburg (Austria). J. Linnerooth. Natural Resources Journal NRJOAB, Vol. 30, No. 3, p 629-660, 1990. 2 tab.

Descriptors: \*Danube River, \*Governmental interrelations, \*International commissions, \*International law, \*Legal aspects, \*Water quality manageal law, \*Legal aspects, \*Water quanty management, \*Water resources management, Competing use, Danube Declaration, Decision making, Environmental policy, International agreements, Planning, Treaties, Water law, Water policy.

The Danube is one of the most international river basins in the world. Recently, representatives of eight European countries bordering the Danube declared their willingness to cooperate on its man-agement, especially in confronting the mounting problems of water pollution. In the absence of a comprehensive, basin-wide planning authority, this Danube Declaration is an important first step in establishing cooperative policies. Any management strategy will involve tradeoffs. Electrical power generation, navigation, and waste disposal, for example, conflict with such uses as irrigation, fisheries, tourism, and supplies of potable water. Irrigation requires enormous quantities of water and may seriously reduce the supply of water for other purposes. The signing ministers of the Danube Declaration have emphasized that a balanced management of the Danube river can be achieved only through cooperation among the eight riparian countries. Establishing that cooperation, especially on improving water quality of the Danube, will be complicated by the power asymmetry between upstream and downstream countries, the scientifically complex and ill-defined nature of the prob-lem, and the lack of a multilateral decision-making river basin authority. In the absence of such a authority, progress can be made only through bilateral agreements covering small bounded seg-ments of the problem. How problems and disputes over the shared uses of water resources have been negotiated and resolved, how past and present institutions have succeeded or failed, and the ways in which the analyst can contribute to the substa tive and procedural issues, are questions of increasing concern if the world is to cope with the expanding menu of transboundary and cross-media environmental problems. In the Shapur and Dalake basin, engineering measures seem promising for salinity control. Among the measures for salt disposal, collection and evaporation of polluted sources in ponds is the most practicable and feasible measure. However, greater benefits can be gained by implementation of salt benefits can be gained by implementation of salt mitigation measures. The model DYRESM was used to simulate the salinity distribution in the planned Jarreh reservoir. Results of the simulation indicate that the Jarreh storage reservoir can regulate and reduce the salt concentration of the irrigalate and reduce the sait concentration or the irriga-tion water to a range between 1500 and 2400 mg/L. Compared with between 1000 and 4200 mg/L for the original river salinity. Furthermore, the diversion of the most saline inflow in summer also decreases salinity. Careful management of the storage reservoir, making use of the natural stratification processes in its water, may further improve the quality of the water releases. (Author's abstract) W91-11432

GROUND WATER CONTAMINATION FROM AGRICULTURAL SOURCES: IMPLICATIONS FOR VOLUNTARY POLICY ADHERENCE FROM IOWA AND VIRGINIA FARMER'S AT-

THYUDES.

New Hampshire Univ., Durham. Dept. of Resource Economics and Community Development.

J. M. Halstead, S. Padgitt, and S. S. Batie.

American Journal of Alternative Agriculture, Vol.

5, No. 3, p 126-133, 1990. 4 tab, 29 ref.

Descriptors: \*Agricultural chemicals, \*Agricultural practices, \*Groundwater pollution, \*Groundwater quality, \*Public opinion, \*Water pollution control, Agricultural runoff, Farm management, Nitrates, Pesticides.

The potential for voluntary adoption of agricultural management practices that reduce risk of groundwater contamination and how farm operators' attitudes regarding the environment might affect the success of voluntary programs are examined. Results from two surveys indicate that farmers' behavior and attitudes in Virginia and Iowa ers' behavior and attitudes in Virginia and Iowa reveal that both groups consider the groundwater issue to be a serious problem to which they are contributing. This awareness is a significant first step in prompting consideration of management practices that reduce the threat to groundwater quality. The surveys also revealed that the worst offenders, i.e., farmers applying nitrogen well above agronomic recommendations, were those with the least concern about the problem. If major which in farming rectifies are a cooper soluntarily. with the least concern about the problem. If major shifts in farming practices are to occur voluntarily, major incentives or disincentives are needed. Even though the concern about groundwater quality is high, the documented risks perceived by farmers are not strongly convincing. The economic incentives for change are questionable at best. Voluntary adoption of best management practices is only one of several policy options. Ultimately, policies designed to reduce groundwater contamination designed to reduce groundwater contamination may need a mix of strategies, including economic incentives and disincentives, zoning and land use restrictions, environmental regulations and bans on agricultural chemicals. Rapid urbanization and industrialization with few environmental controls have made Hong Kong one of the noisiest and most crowded places in the one of the noises and most crowded piaces in the world. Many of Hong Kong's current pollution problems are reminiscent of scenes common in Europe and North America decades ago. The government's first attempt at establishing an environmental department dates back to 1978, when the Environmental Protection Unit (FPI) was created mental department dates back to 1978, when the Environmental Protection Unit (EPU) was created and staffed by just five professional officers. EPU is currently staffed by 700 people and its role includes enforcement and environmental monitor-ing. Other institutional structures have been cre-ated; however, it is still difficult for the public to participate effectively in the formulation and evalparticipate effectively in the formulation and eval-uation of environmental policy measures. Hong Kong has failed to provide significant support for environmental interest groups. Generally, the terri-tory's approach to environmental management is of the command and control type. Hong Kong's

record for effective environmental protection has record for effective environmental protection has been mixed. Curbing industrial source pollution has only begun to be addressed. Although Hong Kong is taking some sweeping actions and is making incremental improvements in a number of areas to reduce pollution levels, overall environmental quality is continuing to decline and many important sources of pollution continue largely unabated because of both the grandfathering system of exemptions, the time requirements for infrastructure development, power of special interest groups and staffing problems. Wastewater treatment

There are about 50 paper and pulp mills in Finland. Pulp and paper production has increased quite rapidly during recent decades. The greatest increase has occurred in the production of bleached kraft pulp and mechanical pulp. Discharge permissions in Finland have recently included total phosphorus and chemical oxygen demand, in addition sions in Finland have recently included total phosphorus and chemical oxygen demand, in addition to the conventional water pollution control parameters of suspended solids and biological oxygen demand. In the near future, requirements for chlorianted organic compounds are also expected. For reducing chlorinated organic compounds, the development of new cooking and bleaching processes will probably be examined. Oxygen delignification will become more common. Other external methods can be developed and improved for the reduction of chlorinated organics. Nutrient loadings can

be reduced by external purification methods. Activated sludge treatment will be the basic method of external purification. The future will bring increased research and development in the area of tertiary treatment. (See also W91-11467) (Mertz-W91-11468

TRENDS IN POLLUTION CONTROL IN THE SWEDISH PULP AND PAPER INDUSTRY. National Swedish Environment Protection Board, Solna. Forest Industry Section.
S. Lagergren, and E. Nystrom.
Water Science and Technology WSTED4, Vol.
24, No. 3/4, p 11-17, 1991. 7 tab.

Descriptors: \*Chlorinated hydrocarbons, \*Pulp and paper industry, \*Pulp wastes, \*Sweden, \*Water pollution control, Bleaching wastes, Chemical wastes, Industrial wastes, Kraft mills, Organic pollutants, White water.

Current production figures, control measures and discharges from the Swedish pulp and paper industry were examined in conjunction with future trends and possibilities. Emphasis was placed on discharges of chlorinated organic substances and internal methods to control such methods. The internal methods to control such methods. In the bulk of discharges come from the manufacture of chemical pulp and within this sector, from kraft (sulfite) pulp. The Swedish National Environmental Protection Agency mandates that each plant should reduce its discharges from the manufacture of unbleached pulp by means that include the following internal process measures: introduction of decreate the more all colories of the section of the of dry bark removal; closure of water systems; effective washing equipment; well developed systems to deal with temporary discharges (spills); and treatment of condensate by steam-stripping and treatment of condensate by steam-stripping and retrieval for further use. The long-term objective is the virtually complete elimination of the discharge of chlorinated organic compounds by the pulp industry. To achieve this requires development of process technology and an almost totally closed water process involving the retrieval and incineration of dissolved substances. Measures adopted to limit discharges into water from the manufacture of mechanical pulps comprise an opti-mal combination of internal process and external features. Internal measures consist of system closures, where water from screening, bleaching and dewatering is circulated to the grinder or refiner. dewatering is circulated to the grinder or refiner.

Another step is to separate contaminated from uncontaminated water. Paper mills are often large, modern units integrated with pulp production. In order to achieve a continuously high degree of closure in integrated paper mills, the supply of white water must be ensured even when variations occur in the flow balances. This minimizes the size of inchestest discharges. The large suppliers are of inadvertent discharges. The large numbers and quantities of chemical additives and coloring agents should be easily degradable and nontoxic. (See also W91-11467) (Mertz-PTT) W91-11469

REGULATORY REQUIREMENTS FOR PULP AND PAPER MILL EFFLUENT CONTROL: SCIENTIFIC BASIS AND CONSEQUENCES. COWIconsult, Lyngby (Denmark).

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 19-31, 1991. 1 fig, 8 tab, 36 ref.

Descriptors: \*Europe, \*Industrial wastes, \*Pulp and paper industry, \*Pulp wastes, \*Water policicy, \*Water policion control, Chemical oxygen demand, Chlorinated hydrocarbons, Hazardous wastes, Hydrogen ion concentration, Stream pollution, Streamed et oblist.

The Ministers' Declaration from the Second North The Ministers' Declaration from the second Nortin Sea Conference recommended the goal of dimin-ishing the discharge of hazardous substances via rivers by 50% over the next 10 years. Discharge reductions of persistent halogenated compounds from pulp and paper mill effluents were adopted by the Paris Convention later. Based on a study conducted for the European Economic Community Commission, the following must be fulfilled to reach this goal: For historic reasons the regulation

### Field 5—WATER QUALITY MANAGEMENT AND PROTECTION

## Group 5G-Water Quality Control

of the pulp and paper industry includes some parameters which may not be the most appropriate ones, for example five-day biological oxygen demand and adsorbable organohalogens. Regulating the bleached pulp mills by absorbable organohalogens/total chlorinated organics is not recommended. Polychlorodibenzo-p-dioxins and polychlorodibenzo furans are very difficult to regulate at present. Regulation of polychlorinated phenolics in the effluent may prove to be a valid indirect measure of tetrachlorodibenzo dioxin equivalents, but this has yet to be novoen. To ensure sufficient this has yet to be proven. To ensure sufficient removal of hazardous compounds, it is recommended that standards for total suspended solids be stringent, as the major fraction of hazardous compounds is associated with suspended solids. Effuent control should be based on pH, chemical oxygen demands using dichromic acid, and total suspended solids and polychlorinated phenolics. At present there are not sufficient data available to establish a regulation based on these parameters. (See also W91-11467) (Author's abstract) W91-11470

GOALS, REGULATIONS AND INFORMATION NEEDS FOR WASTEWATER DISCHARGE MANAGEMENT-AN AMERICAN PERSPEC-TIVE.

National Council of the Paper Industry for Air and

Stream improvement, Inc., New York.
I. Gellman, and W. J. Gillespie.
Water Science and Technology WSTED4, Vol.
24, No. 3/4, p 33-36, 1991.

Descriptors: \*Pulp and paper industry, \*Pulp wastes, \*Regulations, \*Water pollution control, Dioxins, Environmental protection, Industrial wastes, Kraft mills, Water law, Water

The American paper industry currently operates 600 paper mills and 360 pulp mills, of which 124 are in the kraft category. The industry is broadly distributed across the U.S., with half the kraft mills in the South and significant numbers in the Northeast, Midwest and the Pacific Coast regions. National and regional regulations flow from the regularly amended Clean Water Act which provides for a dual approach; technology. The part of the proposed and water the contract of t arry amended clean water Act which provides for a dual approach: technology-based and water quality-based standards. These are implemented in most cases by state agencies operating within a strong oversight structure established by the EPA. strong oversign structure estations and with extensive public participation through the mass communication media and the formal judicial process. Intertwined with a number of information needs is the recognition that some chlororganics have reached trace compound differentiation and detectability limits where disagreements exist over whether there is significant bioresponse. This is the case for 2,3,7,8-dioxin where changes in detectabilcase for 2,3,7,8-droxin where changes in detectability over the past decade from the parts per billion to parts per quadrillion level have been achieved. National assessments of acceptable daily intake levels range from 0.006 to 10 picagram per kg body weight per day, or a range in acceptability from one country to another of over 1000, with the most restrictive limitations in force in the United States. Passes hand debts exercible in second-order States. Research and data assembly is proceeding in all the listed areas on an international scale, as is the development of new regulations. DEVELOPMENT OF ENVIRONMENTAL CONTROL LEGISLATION AND EFFLUENT STANDARDS FOR AUSTRALASIAN WOOD PROCESSING INDUSTRIES.

Forest Research Inst., Rotorua (New Zealand).

Wood Technology Div. J. S. Gifford, and P. N. McFarlane. Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 37-44, 1991. 3 tab, 17 ref.

Descriptors: \*Australia, \*Industrial wastes, \*Legislation, \*New Zealand, \*Water pollution control, \*Water pollution prevention, \*Water quality standards, Environmental protection, Hazardous wastes, Legal aspects, Licensing, Pulp and paper industry, Water policy. The Australasian wood processing industry is poised for a substantial expansion over the next 20 years. Australia, which is presently an importer, is developing plans to become a net exporter of forest products, whereas New Zealand's wood supply is expected to double over this period. In both counexpected to double over this period. In both countries, the expansion of procession capacity will be required to occur in a sustainable and environmentally sound manner. For example, the Australian Federal Government has developed environmental guidelines for new bleached Eucalyptus kraft pulp mills, with the New Zealand government presently enacting a comprehensive Resource Management Act. The Hazards Control Commission, established in conjunction with the Resource Management Act, will be an independent central government body. It will be responsible for controlling the importation, production, use and disposal of hazardous substances and new organisms. For each hazardous substances and new organisms. For each hazardous substances and conscient and operation, production, use and disposal of hazardous substances and new organisms. For each hazardous substances and new organisms. persistence and toxicity to the ecosystem will be assessed as part of the licensing process. This is the first time these considerations will be made in New nd, as previous legislation has focused on the threat to human health and the explosive/flamma-ble nature of the compounds. In addition, the Haz-ards Control Council will be establishing a cradle to grave tracking system for very hazardous sub-stances. (See also W91-11467) (Mertz-PTT) W91-11472

PROCESS INTERNAL MEASURES REDUCE PULP MILL POLLUTION LOAD. Helsinki Univ. of Technology, Espoo (Finland). J. Gullichsen.

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 45-53, 1991. 3 fig, 3 tab.

Descriptors: \*Bleaching wastes, \*Hanford Site process control, \*Pulp and paper industry, \*Pulp wastes, \*Wastewater treatment, \*Water pollution control, Chlorinated hydrocarbons, Chlorine, Environmental protection, Industrial wastes, Lignin, Operating costs

There are several options to modify present pulping processes towards reduced environmental impact. The industry is readily adopting those that have reached the status of proven technology. New process variations are being developed. Process internal measures alone will not be sufficient to reach acceptable levels. External effluent treatment reach acceptable levels. External effluent treatment will always be required. Internal abatement measures should concentrate on reducing pollution potential at the very source but also on improving the conditions for efficient external treatment. Standard unbleached softwood kraft pulp contains roughly 5% lignin after cooking and washing. Hardwood pulp holds considerably less. Increased loss of carbohydrates will be the result if standard cooking procedures are extended a simple by its cooking procedures are extended simply by in-creasing chemicals charge and time. There a sever-al options currently available: polysulfide pulping; anthraquinone additive; extended delignification; oxygen delignification; prenox treatment; alkaline leaching; and improved washing. All measures to reduce the residual lignin content of pulp prior to bleaching will positively affect almost all of the effluent characteristics. Most organochlorides are formed in the bleachplant, mainly as a result of the use of molecular chlorine in the first stage of bleaching. Some are formed in process water purification. Chlorine dioxide can be substituted for fication. Chlorine dioxide can be substituted for chlorine to a significant degree without detrimental effects on bleached pulp quality. Chlorine dioxide produces significantly less organochlorine compounds than chlorine. A prerequisite for efficient effluent treatment is that effluent volumes are kept as low as possible. The overall production cost will increase when applying internal pollution abatement options. The marginal addition is, however, small. (See also W91-11467) (Mertz-PTT)

BIOLOGICAL BLEACHING OF WOOD PULPS-A VIABLE CHLORINE-FREE BLEACHING TECHNOLOGY. Pira, Leatherhead (England). Paper and Board

N. Kirkpatrick.

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 75-79, 1991. 15 ref.

Descriptors: \*Biological treatment, \*Bleaching, Descriptors: "Biological treatment, "Pieacning, Enzymes, "Microorganisms, "Pulp and paper in-dustry, "Water pollution prevention, Biobleaching, Bleaching wastes, Chlorinated hydrocarbons, Mu-tagenicity, Toxicity.

Biobleaching of wood pulp is bleaching caused by the activity of certain microorganisms. The term biobleaching is sometimes also used to describe enzymatic bleaching. In both cases, the aim is to effect bleaching without the use of chlorine, thus minimizing the discharge of potentially toxic and mutagenic chlorinated organics in bleach plant effluents. The current status of biobleaching research is reviewed. On the basis of published information, biobleaching seems unlikely to entirely replace chlorine in a standard bleaching sequence. Therefore, biobleaching, like other alternative strategies such as extended delignification and oxygen bleaching may provide another means of decreasing the load of chlorinated organics in bleach plant effluents. Enzymatic bleaching holds greater promise than whole cell biobleaching. Hemicellulases used in conjunction with alkaline extraction have already been shown to result in significant savings. already been shown to result in significant savings. aiready been shown to result in significant savings.

A Finnish company has run tests on a 1000 metric ton scale in which enzymatic bleaching was shown to economically decrease chlorine consumption by 25-50%. More research is necessary to relate chlorine savings with decreases of bleach plant effluent toxicity and mutagenicity. (See also W91-11467) (Mertz-PTT)

CLOSING PAPER MILL WHITEWATER CIR-CUITS BY INSERTING AN ANAEROBIC STAGE WITH SUBSEQUENT TREATMENT.

Papiertechnische Stiftung fuer Forschung und Ausbildung in Papiererzeugung und -Verarbeitung, Munich (Germany, F.R.). Wasser- und Abwasserforschungsstelle.

R. Huster, I. Demel, and A. Geller. Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 81-90, 1991. 9 fig, 9 ref.

In the past few years, the paper industry has been able to significantly reduce the specific amount of effluent it produces. It is considered that the standeffluent it produces. It is considered that the stand-ard now achieved is not susceptible to improve-ments without a loss of product quality. The prob-lem substances imported with raw materials will tend to increase the specific amount of effluent produced by paper mills that process waste paper, and it will only be possible to operate completely and it will only be possione to operate completely closed circuits in exceptional cases. Integrating a biological purification plant into the whitewater circuit can help to solve this problem, which is specific to waste paper. Operating a purification plant in the half-stuff production sector makes it possible to achieve substantially lower quantities of specific effluent even in integrated paper mills if the water circuits for half-stuff production and for the water circuits for half-stuff production and for the papermachine are kept largely separate, and if the freshwater intake is effected via the paperma-chine's circuit. The use of anaerobic technology, with appropriate subsequent treatment if necessary, appears suitable because of its favorable energy balance. The possibilities and limits of using anaerobic technology for treating highly concentrated effluents from paper mills are largely known. The use of this technology in the whitewater circuits of paper mills is still in the planning stage. Simple model calculations can be used to estimate the effects of operating a purification plant on the equilibrium concentrations in the whitewater circuit and to detect possible problems. ## ENVIRONMENTALLY DESIRABLE APPROACHES FOR REGULATING EFFLUENTS FROM PULP MILLS,

Sprague Associations Ltd., Guelph (Ontario). J. B. Sprague.

Water Science and Technology WSTED4, Vol. 24, No. 3/4, p 361-371, 1991. 4 tab, 31 ref.

Descriptors: \*Environmental policy, \*Environmental protection, \*Pulp wastes, \*Regulations, \*Wastewater outfall, \*Water pollution control, Australia, Chlorinated hydrocarbons, Discharge limits, England, Finland, Sweden, Toxicity, United States

An overall strategy of regulation should always include three tactics: (1) discharge limits at the end include three tactics: (1) discharge limits at the end of the effluent pipe, based on a reasonable level of industrial technology; (2) water quality-based limits, strict enough to eliminate sublethal effects beyond a mixing zone; and (3) periodic ecological surveys to check the effectiveness of the first two approaches. Sets of increasingly restrictive Levels of Achievement should be formulated to provide steps for management. The final level should represent an ultimate goal of eliminating deleterious seeps for management. He mina level's mount repre-sent an ultimate goal of eliminating deleterious discharges, for example the effluent-free mill. Recent Australian regulations for kraft mills give a balanced blend of all three tactics. Federal require-ments in the U.S. also have the three tactics, with good water quality limits for sublethal toxicity, but a blind spot for organochlorines. Canadian federal regulations continue to focus only on tactic no. 1, with little acknowledgment of the receiving ecosystems, although some provinces add that. Both Sweden and Finland regulate by discharge limits, Sweueri and Finiand regulate by discharge limits, but from a background of site-specific knowledge and needs. There are relatively uniform sites in the Baltic for Swedish mills, but a diversity of freshwater locations for Finnish ones. (See also W91-11467) (Author's abstract) W91-11504

## ESTIMATION OF SPORT FISH HARVEST FOR RISK AND HAZARD ASSESSMENT OF ENVIRONMENTAL CONTAMINANTS,

Battelle Pacific Northwest Labs., Richland, WA. T. M. Poston, and D. L. Strenge.
Available from the National Technical Information Avanaole from the National Technical Information Service, Springfield, VA. 22161, as DE89-011210. Price codes: A03 in paper copy, A01 in microfiche, Report No. PNL-SA-16365, January 1989. 28p. 1 fig. 7 tab, 45 ref. DOE Contract DE-AC06-76RLO 1830.

Descriptors: \*Sport fishing, \*Risk assessment, \*Ecological effects, \*Path of pollutants, \*Fish harvest, Recreation, Public health, Toxicity, Sunfish, Bass, Fish populations, Bioaccumulation, Food chain, Lipids, Fish, Muscle.

Consumption of contaminated fish flesh can be a significant route of human exposure to hazardous chemicals. Estimation of exposure resulting from the consumption of fish requires knowledge of fish consumption and contaminant levels in the edible portion of fish. Realistic figures of sport fish harvest are needed to estimate consumption. Descrip-tive statistics based on fishing pressure were de-rived from harvest data for four distinct groups of freshwater sport fish in three water types: streams, lakes, and reservoirs. Statistics were also developed for all fish harvested from a single site. Regression equations were developed to relate har-vest to surface area fished, where databases were sufficiently large; using the bioaccumulation factor and the concentration of contaminants in water as and the concentration of contaminants in water as variables in the exposure equation may also lead to less precise estimates of tissue concentration. Harvest estimates were developed for all species harvested and for 4 distinct groups of sport fish: bass, sunfish, trout, and catfish. Mean harvest rates for all species combined ranged from 0.575 fish/hr in cold water streams to 0.934 fish/hr in warm water traces. cold water streams to 0.934 hish/hr in warm water streams. The majority of trace metals are biologically available in water at low concentrations (ppb to low ppm) because they have a strong propensity to sorb to sediment and suspended material, or to form complexes with inorganic ligands. Generally, trace metals exhibit little tropism for fish muscle. Only Cr and Hg have shown an age-dependent increase in fish tissue concentration from samples increase in fish tissue concentration from samples collected in the field. Mercury is perhaps the only metal that has shown a propensity to accumulate in egible portions of fish and it has therefore been of great concern in Japan, Sweden and elsewhere. The influence of percentage of body lipids has been raised as a significant factor when estimating bioaccumulation factors in fish. Certain species of fish tend to contain more limit then others: however, the property of the contain more limit then others: however, the contain more limit then others however. bloaccumulation factors in itsh. Certain species or fish tend to contain more lipid than others; howev-er, the fish's breeding rate, the caloric content of its food, its age, and its physiological status will affect its lipid reserves. Generally, mean lipid levels for freshwater fish fillets range from 0.2 to nevers for treshwater fish fillets range from 0.2 to 7.7. Methods based on normalized bioaccumulation factors, maximum permissible tissue concentrations and percentage lipid in fish tissue have been proposed by the US EPA to determine acceptable tissue residue levels for fish. ## Water Quality Control-Group 5G

The Intel (Mountain View Plant) site is one of three Superfund sites in the Mountain View, Cali-fornia, area that are being remediated concurrent-ly. Various industrial activities were conducted in ly. Various industrial activities were consumed the vicinity of the site, including semiconductor the vicinity of the site, including semiconductor manufacturing, metal finishing operations, parts cleaning, aircraft maintenance, and other activities requiring the use, storage, and handling of a variety of chemicals, particularly solvents. Site investingations at several of these facilities during 1981 and 1982 revealed significant soil and groundwater contamination by toxic chemicals, primarily volatile organic compounds (VOCs). The primary causes of the contamination were leaking storage tanks and lines, and poor management practices. tanks and lines, and poor management practices. Before and during additional site investigations, which were conducted under a 1985 Consent Order, interim cleanup actions were conducted at the site by Fairchild, Intel, and Raytheon. These the site by Fairchild, Intel, and Raytheon. These included tank removals, soil removal and treatment, well sealing, construction of slurry walls, and hydraulic control and treatment of local groundwater. The primary contaminants of concern affecting the site are VOCs including trichlor-oethylene, trichloroethane, tetrachloroethylene, toluene, and xylenes; and other organics including phenols. The selected remedy for this site includes in situ vapor extraction with treatment by vapor hasse granular activated earbox (GAC) of conin situ vapor extraction with treatment of vapor phase granular activated carbon (GAC) of contaminated soil found within the Fairchild and Raytheon slurry walls. There may be some limited soil excavation and treatment by aeration for some areas outside of the slurry walls with on-site disareas outside of the slurry walls with on-site dis-posal of residues in the excavated area; groundwat-er pumping and treatment using air stripping, and in some cases liquid phase GAC, with emissions controls consisting of GAC vapor phase carbon units, followed by reuse of the groundwater (reuse options including reinjection are being developed) and if necessary discharge to surface water, sealoptions including temperation are being everloped) and, if necessary, discharge to surface water; sealing of any conduits or potential conduits to protect the deep aquifer; and groundwater monitoring. The present worth cost for this remedial action is \$49,000,000 to 56,000,000, which includes operation and maintenance costs. (Author's abstract)
W91-11581

## SUPERFUND RECORD OF DECISION: WHIT-MOYER LABORATORIES, PA.

MOYER LABORATORIES, PA. Environmental Protection Agency, Washington, DC. Office of Emergency and Remedial Response. Available from the National Technical Information Service, Springfield, VA. 22161, as PB90-114661. Price codes: A04 in paper copy, A01 in microfiche. Report No. EPA/ROD/R03-89/075, June 1989. 46p, 3 fig, 3 tab, append.

Descriptors: \*Cleanup operations, \*Pennsylvania, \*Site remediation, \*Superfund, \*Whitmoyer Lab-oratories Site, Arsenic, Biodegradation, Costs, Groundwater pollution, Heavy metals, Landfills, Tetrachloroethylene, Volatile organic compounds, Wastewater treatment, Water pollution treatment.

The 22-acre Whitmoyer Laboratories site is located in Jackson Township, Lebanon County, Pennsylvania. Land use surrounding the site is predominantly agricultural; however, there is some residential, commercial, and industrial development within 1.5 miles of the site. This includes a manufacturing plant to the south; a pharmaceutical fac-tory to the east; a large, active limestone quarry to tory to the east, a large, active innessione quarry to the west; and an elementary school to the north-west of the site. Portions of the site are within neighboring Tulpehocken Creek's 100-yr flood-plain. In 1957 site owners began producing organic arsenicals at the site. In 1964 widespread groundwater contamination was discovered on-site lead-ing to the placement of concentrated wastes in a concrete vault and the initiation of groundwater pumping and treatment. Sludges from the groundpumping and treatment. Sludges from the ground-water treatment were later consolidated in lagoons. In 1987 an EPA investigation revealed that ap-proximately 69,000 gallons of concentrated liquids had been abandoned on-site in 18 tanks and 14 piping units. The wastes include 5,000 gallons of water-immiscible liquids, 25,000 gallons of water-miscible liquids with a high arsenic content, and 39,000 gallons of water-miscible liquids with a low arsenic content. Flooding of the creek could cause failure of these tanks, resulting in a catastrophic failure of these tanks, resulting in a catastrophic

### Field 5—WATER QUALITY MANAGEMENT AND PROTECTION

## Group 5G-Water Quality Control

release of contaminants to the creek. Because the concentrated liquids pose significant health and environmental threats, their removal is addressed in this first operable unit. The primary contami-nants of concern in the concentrated liquids are nants of concern in the concentrated liquids are volatile organic compounds including tetrachlor-oethylene, and metals including arsenic. The selected interim remedial action for this site includes consolidating and transporting off-site, and then treating, using thermal treatment or biodegradation, or recycling approximately 69,000 gallons of concentrated liquid wastes at a permitted Resource Conservation and Recoveryr Act (RCRA) facility, followed by disposing of treated water in off-site surface water and disposing of solid residues in an off-site landfill; decontaminating 32 tanks and approximately 2,000 ft of piping to meet RCRA out-site landfill; decontaminating 32 tanks and approximately 2,000 ft of piping to meet RCRA Subtitle C closure standards and disposing of the tanks and piping on-site; and treating and disposing of the cleaning agent residues off-site at RCRA-permitted facilities. The estimated capital cost of this interim remedial action is \$475,000, with no operation and maintenance costs. (Lantz-PTT) W91-11582

STATUS REPORT ON REMEDIAL INVESTI-GATION OF THE 300 AREA PROCESS PONDS. GATION OF THE 300 AREA PROCESS PONDS, Battelle Pacific Northwest Labs., Richland, WA. D. I. Dennison, D. R. Sherwood, and J. S. Young. Available from the National Technical Information Service, Springfield, VA. 22161,as DE90-003667. Price codes: A05 in paper copy, A01 in microfiche. Report No. PNL-6442, September 1989. 75p, 14 fig. 10 tab, 5 ref, 2 append. DOE Contract No. DE-AC06-76RLO 1830.

Descriptors: \*Pollutant identification, \*Process ponds, \*Remedial investigation, \*Site remediation, \*Water pollution sources, Aluminum, Cesium radioisotopes, Chromium, Cobalt radioisotopes, Copper, Heavy metals, Nickel, Organic compounds, Path of pollutants, Polychlorinated biphenyls, Sediment contamination, Silver, Zinc.

A remedial investigation (RI) of the South and North Process Ponds adjacent to the 300 Area at the US Department of Energy (DOE) Hanford Site was initiated in FY 1987 as partial implementation of the DOE Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Program. The objective of FY 1987 activities was initial characterization of the quantity and distribution of contaminants in the active and distribution of contaminants in the active. ty and distribution of contaminants in the sedi-ments. Sediment samples from 14 locations in and adjacent to the ponds were collected and analyzed. Initial results indicated that contaminated sediments in the ponds typically contained Ag, Al, Cr, Ni, and Zn that were elevated relative to background levels. Radiochemical analyses of the sediments showed that the primary radiological contaminant was uranium; 60-Co and 137-Ce were detected in several samples. Future RI activites will be undertaken under EPA-approved RI/FS work plans. (Author's abstract) W91-11583

ASSESSMENT OF INTERNATIONAL TECHNOLOGIES FOR SUPERFUND APPLICA-

Environmental Protection Agency, Washington, DC. Office of Solid Waste and Emergency Re-

sponse.

Available from the National Technical Information Service, Springfield, VA. 22161, as PB90-106428. Price codes: A05 in paper copy, A01 in microfiche. Report No. EPA/540/2-88/003, September 1988. 50p, 1 fig. 4 tab, 13 append. EPA Contract No. 68-03-3243.

Descriptors: \*Cleanup operations, \*Site remediation, \*Superfund, \*Water pollution treatment, Air stripping, Belgium, Biological treatment, Cadmium, Chemical treatment, Electrochemistry, Extraction, Germany, In situ treatment, Incineration, Technology, The Netherlands.

Several international technologies were identified and investigated for their applicability to hazard-ous waste site remediation in the United States. The program was conducted in two phases: Phase I involved technology identification and selection;

Phase II was an investigation of the most promis-ing technologies identified in Phase I. This report summarizes the results of Phase II. The field team visited with twelve research groups, consultants and manufacturers at 15 locations in The Netherlands, Belgium and the Federal Republic of Ger-many. Results of the individual site visits are summany. Results of the individual site visits are sum-marized and a capsule summary of each technolo-gy includes a brief process description, discussion of process levelopment. In general, the Phase II efforts were successful at identifying site cleanup technologies not currently used in the United States, as well as unique applications of techniques used in the United States. Among the most important Phase II findings were five differ-ent soil washing techniques in Holland and Germa-ny. Another key finding was the High Tempera-ture Slagging Incinerator technology reviewed in Belgium. In addition, the field team reviewed unique applications of in situ biological treatment and composting techniques, vacuum extraction and and composting techniques, vacuum extraction and in situ air stripping, in situ extraction of cadmium from soils, application of rotating biological contractors, and electrochemical dehalogenation techniques. niques. NUTRIENT LOADING STATUS OF THE CON-ESTOGA RIVER BASIN, 1985-1989. Susquehanna River Basin Commission, Harrisburg, PA. Resource Quality Management and Protection

A. N. Ott. Susquehanna River Basin Commission, Harrisburg, Pennsylvania. Publication No. 133, April 1991. 14p. 4 fig. 3 tab.

Descriptors: \*Conestoga River Basin, \*Nutrients, \*Pennsylvania, \*Phosphorus, \*Pollutant load, \*Water pollution cources, Monitoring, Municipal wastewater, Nitrogen, Stream discharge.

The Conestoga River at Conestoga, PA, one of 14 Pennsylvania sites monitored by the Susquehanna River Basin Commission for its nutrient loading content from 1985 to 1989, was the only site to show a significant change in loading. Annual nitrogen loads indicated a good relationship (no change in loading) with the mean annual stream discharge, while the phosphorus load for 1988 and 1989 showed a decreased loading. Monthly base flow phosphorus concentrations were significantly lower during June 1988 to December 1989 than for the January 1985 to May 1988 period. Records provided from the City of Lancaster, PA sewage treatment plant (STP) showed substantial reduction in phosphorus effluent loadings in 1988 and 1989 in contrast to the loadings of prior years. Conestoga River phosphorus load reduction in 1988, but the STP reduction in 1989 accounted for only a part of the 1989 river reduction. (Author's abstract)

REGIONAL APPROACH TO DROUGHT PLANNING AND MANAGEMENT IN THE GREAT LAKES BASIN.

Great Lakes Basin Commission, Ann Arbor, MI. T. R. Crane, R. C. Damberg, and M. J. Donahue. IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 79-91, 2 fig,

Descriptors: \*Drought, \*Great Lakes, \*Interna-tional agreements, \*Interstate compacts, \*Water resources management, Data acquisition, Illinois, Indiana, Information exchange, Interstate commis-sions, Michigan, Minnesota, Monitoring, New York, Ohio, Ontario, Pennsylvania, Quebec, Water deficit, Wisconsin.

The 1988 drought caused the international Great Lakes Basin to suffer losses in agricultural produc-tivity, increased public costs, and the economic and environmental consequences of lowered water levels and water scarcity. The crisis response situalevels and water scarcity. The crisis response situation prompted numerous state, provincial, and federal legislative policy initiatives and emergency programs. Current policies and programs in many areas touched by the drought were called into question, and the debate over Great Lakes water diversion was renewed. The Great Lakes Commission established drought management as a priority issue in November 1988 in response to the impacts of that year's drought on various sectors of the Great Lakes economy and environment. A project to assist local, state, provincial, and federal officials in establishing a coordinated, regional planning in establishing a coordinated, regional planning framework for drought management was proposed

## Techniques Of Planning-Group 6A

at the Commission's Annual Meeting on November 10, 1988. The first action taken by the Great Lakes Commission in the area of drought management was to create a Drought Management and Great Lakes Water Levels Task Force. Members of the Lakes Water Levels Task Force. Members of the Task Force represent the eight states bordering the Great Lakes (MN, WI, IL, MI, OH, PA, NY), the province of Ontario, and several federal agencies. Recommendations of the drought management task force were: (1) development of a Federal Drought Task Force; (2) development of State/Provincial task forces; (3) expanded data collection and dissemination; (4) increased monitoring of drought conditions and water levels; and (5) establishing intermediate and long-term planning activities. BREAKING THE INCREMENTALIST TRAP:
ACHIEVING UNIFIED MANAGEMENT OF
THE GREAT LAKES ECOSYSTEM.
Cornell Univ., Ithaca, NY. Dept. of Civil and
Environmental Engineering.
D. J. Allee, and L. B. Dworsky.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 213-227, 12

Descriptors: \*Ecosystems, \*Great Lakes, \*Institu-tions, \*International Joint Commission, \*Interna-tional commissions, \*Water resources manage-ment, Management planning, Public policy, Water

In normal times only small changes in policy can find agreement. Large changes generate too much uncertainty and objection to be adopted. But what is normally more than an incremental policy change can become incremental under crisis. The greater the sense of crisis the more it can be expected that there will be support to act and to ignore at least some objections that would become road blocks in normal times. Such policy change windows can be created by Great Lakes related events such as fish consumption bans or extreme water levels. A definition of the Great Lakes as an ecosystem and the application of that definition suggests the basis for the development of more policy windows as well as the current need for issue resolution. Nongovernmental organizations will play an important role but so will the states and provinces. Two incubation opportunities provide new and nonincremental opportunities to In normal times only small changes in policy can and provinces. Two incubation opportunities provide new and nonincremental opportunities to meet the challenge of devising means to manage the Great Lakes as an integrated ecosystem. The first incubator is structured around the current wide ranging effort of the International Joint Commission (IJC) and the carrying out of its responsibilities of the Great Lakes Water Levels Reference. The second incubation opportunity would have the creation of an Ecosystem Study Board be the outgrowth of a new study to gain a Great Lakes ecosystem perspective, per se, not tied to Lakes ecosystem perspective, per se, not tied to any issue but the need for such a perspective. The any issue but the need for such a perspective. The opportunity provided by the second incubator build on the strengths already in place or developing for managing a Great Lakes Integrated Ecosystem. Some of the strengths are: experience under the Great Lakes Water Quality Agreement; commitment to the ecosystem approach; perceptions and philosophies expressed by the IJC on the need for a broader Ecosystem approach; the wide range. for a broader Ecosystem approach; the wide rang-ing reports compiled by IJC task forces established by formal References on matters other than water quality identifying linkages to other issues; the accumulation of national and international arrangeaccumulation of national and international arrange-ments under quasi-formal or informal agreements among governments and non-governmental enti-ties; and, the capacity of modern computational equipment to model complex multi-objective and multi-functional problems. GREAT LAKES WATER LEVELS MANAGE-MENT: RELAXING THE 'POLICY TRAP'. Toronto Univ. (Ontario). Inst. for Environmental

A. P. Lino Grima.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 241-247, 15

Descriptors: \*Great Lakes, \*International Joint Commission, \*Water level, \*Water resources man-agement, Fluctuations, Political aspects, Public policy, Regulated flow, Resources management,

The current study of Great Lakes water levels presents an opportunity to examine policies that enhance resiliency and relax the 'social trap', i.e. the cyclical pattern of developing and protecting hazard-prone shoreline. Since 1964, the fluctuaitions of Great Lakes water levels have been the subject of four studies by the International Joint Commission (IJC). Previous studies have demonstrated that Great Lakes water levels are already efficiently regulated by nature; further efforts to control water levels are limited in scope and costly to implement. These technical findings are not likely to be drastically changed. Therefore, the political-education function of the current studies political-education function of the current studies assumes a special significance. The current study is being carried out in a context of uncertainty: some predict a reduction in average runoff of 20% due to climate change and a further reduction in water levels due to increased consumptive water uses. The context of uncertainty makes it even more important to from on extrateries to cope with the The context of uncertainty makes it even more important to focus on strategies to cope with the fluctuations in water levels rather than regulate them. A suggested comprehensive approach to reduce flood and erosion damage would include mapping hazard-prone shorelines as a basis for land use regulations backed by economic incentives and legal penalties. An appropriate split of jurisdictional responsibilities is required. (See also W91-11003) (Author's abstract)

REGULATION OF LAKE ONTARIO LEVELS. Corps of Engineers, Buffalo, NY. Water Quality

In: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 249-258, 2 fig.

Descriptors: \*Great Lakes, \*Lake Ontario, \*Regulated flow, \*Water resources management, Decision making, Great Lakes/St Lawrence River Basin, Management planning.

During the past 30 yrs, the Great Lakes have experienced periods of drought and high water. Throughout this time, the levels of Lake Ontario have responded to these climatic changes and have been modified by regulation. The present regulation plan for Lake Ontario is referred to as Plan notes that the present regulation of the present regulation plan for Lake Ontario is referred to as Plan. 1958-D. The plan specifies outflows which are subject to various criteria and limitations in order subject to various criteria and immandis in order to provide overall benefits to interests throughout the Lake Ontario/St. Lawrence River basin. A degree of discretion is also included among the plan criteria to enable response to conditions outside the range upon which the plan was developed. Recent high and low supply conditions have resulted in much concern regarding the plan's re-Recent high and low supply conditions have re-sulted in much concern regarding the plan's re-sponsiveness. As a result, the plan is being critical-by reviewed with the objective of establishing a new method which would respond more quickly to changing supplies and address interests not pre-viously considered. The final outcome of this viously considered. The final outcome of this review will most likely be a dynamic regulation procedure: a combination of a regulation plan guided by hydrologic-based forecasting models. The procedure will be 'dynamic' in that it will be flexible to the incorporation of future regulation improvements and operational experience. Discretionary actions will be formalized to some degree, however, they cannot be eliminated since future

supply conditions will likely remain unknown. (See also W91-11003) (Lantz-PTT) W91-11028

SUCCESSES AND CHALLENGES IN DEVELOPING AND IMPLEMENTING REMEDIAL ACTION PLANS TO RESTORE DEGRADED AREAS OF THE GREAT LAKES.

International Joint Commission-United States and Canada, Windsor (Ontario).

J. H. Hartig, L. Lovett-Doust, and P. Seidl IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 269-278, 1 fig,

Descriptors: \*Great Lakes, \*International Joint Commission, \*Lake restoration, \*Remedial Action Plans, \*Water pollution control, \*Water resources management, International commissions, Management planning, Resources management, Water quality control.

Forty-two Areas of Concern have been identified in the Great Lakes Basin Ecosystem where general or specific objectives of the Great Lakes Water Quality Agreement are not met and where such failure has caused or is likely to cause impairment of beneficial use or of the area's ability to support aquatic life. The eight Great Lakes States and the aquatic life. The eight Great Lakes States and the Province of Ontario have committed to developing and implementing a Remedial Action Plan (RAP) to restore beneficial uses in each Area of Concern within their political boundaries. RAPs are to idenwithin their political boundaries. KAP's are to iden-tify when specific remedial actions are to be taken to resolve these problems, and who is responsible for implementing them, in an effort to increase accountability. The International Joint Commis-sion believes that successful remediation of Areas of Concern depends on the full and effective involvement of all stakeholders. Selected successes include enhanced cooperation and communication and greater emphasis on contaminant control at source, and assessment and remediation of con-taminated sediments. Remaining challenges include limited resources, a need to assign responsibility for remedial actions, and the need to integrate RAPs into state, provincial and federal priorities. (See also W91-11003) (Author's abstract) W91-11030

SOCIO-ECONOMIC CONSIDERATIONS IN REMEDIAL ACTION PLANNING FOR THE GREAT LAKES—A CASE STUDY FOR SUSTAINABLE DEVELOPMENT.

Canada Centre for Inland Waters, Burlington (Ontario).

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 279-287, 4 ref.

Descriptors: \*Economic aspects, \*Great Lakes, \*Lake restoration, \*Ontario, \*Remedial Action Plans, \*Social aspects, \*Water pollution control, \*Water resources management, Canada, Case studies, Management planning, Provincial jurisdiction, Public policy, Water resources development.

Early in the process of remedial action planning (RAPs), it was recognized that socio-economic considerations would be a necessary component of any completed plan involving public expenditures. any completed plan involving public expenditures.

A discussion document on socio-economics in RAPs was produced and released to the 17 Canadian RAP coordinators to encourage them to include socio-economic studies apart of the planning process. To date, socio-economic studies have been conducted for two Access of Comment Facility. been conducted for two Areas of Concern, Hamil-ton and Bay of Quinte, and an economic overview of the entire RAP process in Canada-Ontario is being conducted by the provincial Ministry of the being conducted by the provincial Ministry of the Environment. Since the remedial measures will likely involve a sustainable redevelopment of the area extending beyond the water body, there is a need to consider RAPs from a broad ecosystem perspective including humans and societal activi-ties. Socio-economic information is crucial if pub-licly responsible and defensible decisions are to be made on these issues through the multi-disciplined/ made on these issues through the multi-disciplined/

## Group 6A—Techniques Of Planning

interested stakeholder/public advisory process. Only two such studies have been completed so far, and these have met with resistance from the stakeholders to the RAP process. Reasons for this resistance need to be understood and addressed for any new studies. Benefit cost analysis should not be used for the consideration of RAP socio-economic desirability. Rather, a series of studies are needed that provide timely information to support the public involvement process leading to the prepara-tion and implementation of the RAP. Historical, current and past uses need to be identified in socioeconomic terms. Long-term sustainable use goals for the areas of concern need to be developed based on the social and economic consequences of redevelopment. Timely and cost-effective imple-mentation of the remedial actions, from a societal perspective, needs to be identified for implementation. Finally, there is a need to audit and revise the plans based on the degree to which the societal goals of the RAP are achieved. (See also W91-11003) (Lantz-PTT) W91-11031

FLUCTUATING GREAT LAKES WATER LEVELS: PROGRESS AND OPPORTUNITIES. International Joint Commission-United States and

International Joint Commission-United States and Canada, Ottawa (Ontario).

M. Clamen, and D. F. Parsons.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 289-297, 5 ref.

Descriptors: \*Fluctuations, \*Great Lakes, \*Great Lakes/St Lawrence River Basin, \*International Joint Commission, \*Water level, \*Water resources management, Ecological effects, Ecosystems, Environmental impact, International commissions, Political aspects, Public policy, Regulations.

On August 1, 1986, during a time of record high water levels on all the Great Lakes except Lake Ontario, the Governments of Canada and the United States requested the International Joint Commission (IJC) to examine and report upon Commission (IJC) to examine and report upon methods of alleviating the adverse consequences of fluctuating water levels in the Great Lakes-St. Lawrence River Basin. The IJC interpreted the Governments' request as requiring a more comprehensive study than had been undertaken in any of the previous IJC investigations on this topic. The Commission has responded to the Reference in a number of ways, including submission of initial letter reports to Governments in November and December 1986 an Interim Report in November. December 1986, an Interim Report in November 1988, and establishment of a Project Management Team (PMT) in June 1987 to undertake the first phase of this broad comprenensive study. In 1989 the Commission released reports produced during Phase I for public review and comment, the phase steaming for the final phase. Seven ase of this broad comprehensive study. In midand began planning for the final phase. Seven Annexes were prepared by the PMT's work groups; the Progress Report was drawn primarily from the Annexes, but with separate conclusions and recommendations. Additional findings, conclusions sions and recommendations are contained within the various Annexes and area those of the individual groups. The subjects of the seven Annexes are: Past and future water level fluctuations; Environmental features, processes and impacts-an ecosystem perspective on the Great Lakes-St. Lawrence River System; Interests, policies and decision making-prospects for managing the water level issues in the Great Lakes-St. Lawrence River Basin; The Great Lakes ecosystem perspective implications for water level management; Potential actions to deal with the adverse consequences of fluctuating water levels; Evaluation instrument; and, Public information program. WHAT STAKEHOLDERS WANT AND WHY.

Gore and Storrie Ltd., Toronto (Ontario). L. Ludlow, and K. O'Grady. IN: International and Transboundary Water Re-

sources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 319-328, 1

Descriptors: \*Institutional constraints, \*Public participation, \*Water resources management, \*Water use, Cost-benefit analysis, Costs, Land use, Regula-

Interests make investments in order to capture flows of services from the lakes and/or the channels of the Great Lakes Basin. In so doing, the interests employ expectations of how future events are likely to affect future welfare. These expectations form the basis of the positions held by the interest and, as such, provide an impetus behind petitioning for government action. Petitioning can arise from a number of sources including: (1) surject Dake of resiliency. (3) cost shifting, and (4) arise from a number of sources including: (1) sur-prise, (2) lack of resiliency, (3) cost shifting, and (4) benefit enhancement. In examining the interests' positions, several main points emerge. Surprise and lack of resiliency appear to underlie much of the petitioning. Considerable disagreement exists be-tween and within groups as to the desirability of level regulation measures. Any action initiated by a level of government to address the issue of fluctua-tions, including the decision to do nothing, is de-fined as a measure. The five broad classes of measfined as a measure. The five broad classes of measures which governments could implement to address the fluctuating water levels issue are: Type 1--regulation and diversion; Type 2--direct government investment for adoption and protection (e.g. shore protection works); Type 3-direct restrictions on land and water use (e.g. set back and zoning requirements, ship navigation procedures); Type 4-programs to indirectly influence use (e.g. aype --programs to indirectly influence use (e.g. hazard mapping, information and education programs); and Type 5--emergency response. Aside from those interests seeking level regulation, most interests either petition for maintenance of the status quo or seek more localized measures. There status quo or seek more localized measures. I nere is no unified support for any particular localized measure except, perhaps, a broad support for measures providing a variety of information. Descriptors: \*Decision making, \*Great Lakes, \*Institutional constraints, \*International Joint Commission, \*Water resources management, Governmental interrelations, Water level.

The complex institutional setting for Great Lakes governance is a reality that must be accommodated in any attempt to improve management of Great Lakes water level issues. Efforts to establish meas-Lakes water level issues. Efforts to establish measurable goals and objectives for institutions, systems of accountability, performance evaluation procedures, and mechanisms to withdraw marginal institutions, have more potential for improving institutional effectiveness than creation of any new, omnipotent regional authority. A critical shortcoming of the present institutional setting is the lack of established forums for alternatives dispute resolution (ADP) processes that can forter returnal learn tion (ADR) processes that can foster mutual learning among interest groups, including government agencies. For disputes with a strong technical dimension, ADR uniquely offers the potential for groups to change their positions based on learning that occurs through direct dialogue with other groups. Commitment to use ADR processes as a first approach for managing disagreements over water level issues does not require additional International Joint Commission (IJC) authority; existing provisions of the Boundary Water Treaty of 1909 are sufficient. For local water level issues. effective tion (ADR) processes that can foster mutual learnare sufficient. For local water level issues, effective forums could be provided by federal, state/provincial, or regional agencies (interstate and intrastate)

provincial) that have no direct involvement in decision making concerning the specific issue, or by non-governmental organizations that have broad resource management interests and are capable of impartial and independent functions. (See also W91-11003) (Lantz-PTT)

SO WHAT, FINDINGS AND RECOMMENDA-TIONS FROM THE LAKE LEVELS STUDY. Virginia Polytechnic Inst. and State Univ., Blacks-burg. Dept. of Agricultural Economics. L. Shabman, and B. Smit.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 339-348, 2 ref.

Descriptors: \*Government interrelations, \*Great Lakes, \*Institutional constraints, \*Water level, \*Water resources management, Communication, Decision making, Information exchange, Public

The recommendations presented in the paper evolve from findings relating to the positions of the interests, policies of governments, and institutional organizations and decision making processes; they organizations and decision making processes; they are addressed to the federal governments. In general, governments must improve their ability to inform interests, both about the nature of the physical system and about the policies and programs to direct use of the basin's resources. More specifically, governments should clarify and articulate their course respecibilities, define and develop appropria 19, governments should charry and articulate their own responsibilities, define and develop appropriate information bases, and establish and commit to the use of vehicles for improved communication between interests. Communications can be facilitated using Alternative Dispute Resolution (ADR) procedures within the confines of the Boundary aters Treaty as it stands at present. Governments should also make clear that measures to regulate levels are unlikely to be implemented in the fore-seeable future. (See also W91-11003) (Author's abstract) W91-11037

It has become increasingly clear that the Great Lakes Basin needs some kind of effective and enforceable comprehensive water management plan

## **Evaluation Process—Group 6B**

if it is to effectively stave off growing water diver-sion and pollution threats to the integrity of the Lakes. One of the primary barriers to development of a comprehensive plan for managing the water resources the Great Lakes, has been a lack of 'political will' on the part of the member states. While informal, cooperative water resources manwhite infolmai, cooperative water resources man-agement efforts are being undertaken to develop such a program, valuable political lessons can be gained by examining the development of the formal federal-interstate regulatory compact used to manage the Delaware River Basin. Several fac-tors seem to have led to the formation of the tors seem to have led to the formation of the federal-interstate compact governing the Delaware River Basin. But, as one expert on the Delaware River Basin Compact stated, the primary ingredients for creating institutions such as the Delaware River Basin Compact are time and political will. The alleged lack of political will in the Great Lakes region, which apparently resulted in the formation of a weak Great Lakes Commission, may in part be attributed to a lack of consensus as to what type of institutional arrangement would be may in part be attributed to a lack of consensus as to what type of institutional arrangement would be most appropriate for the various member states. This determination of the appropriate institutional framework for governing the Delaware Basin was not a problem because of an impressive plan for governmental organization of the Delaware River Basin. Many of the preconditions that helped marshall the necessary political will of the Delaware Basin to form a federal-interstate compact also exist in the Great Lakes Basin. Considering the historical similarities of the two basins, it is not inconceivable that some triggering event such as another drought and/or a new out-of-basin diveranother drought and/or a new out-of-basin diver-sion threat could serve as a catalyst to force movement away from the status quo arrangement of the existing Great Lakes Basin Compact. There is no legal barrier to including Canada as a signatory party to any compact; therefore Canada is a critical party to any comprehensive water resource management plan for the Great Lakes Basin. Fed-eral participation in a new or revised federal-interct may reduce the opposition to formal Canadian involvement that surfaced in the lengthy Congressional approval process of the existing Great Lakes Basin Compact. COMPREHENSIVE WATER MANAGEMENT STRATEGY: CREDIT RIVER WATERSHED. Triton Environmental Consultants Ltd., Burnaby (British Columbia).

(Brussa Columbia). R. H. Tufgar, H. Whiteley, and H. Bretton. IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 405-418, 2 fig. 5 tab, 10 ref.

Descriptors: \*Credit River Basin, \*Water management, \*Water resources management, Environmental impact, Erosion, Fisheries, Flooding, Recreation, Water quality.

The Credit River Watershed is experiencing signif-Ine credit River watershed is experiencing significant urban growth which has created concerns regarding potential impacts on flood potential, erosion base flow and water quality. Water quality impacts could threaten the continuation of the existing cold water fisheries resource, water-based recreation activities, and environmentally sensitive areas. In order to preserve the integrity of the Credit River, the Credit Valley Conservation Authority carried out a study to develop a Water Management Strategy for the watershed. The study included a detailed technical assessment of the impacts of development on the flow regime characteristics and related impacts including flood potential, erosion potential and base flow. Environmental and public issues reviewed in the study were placed into three resource categories: (1) fisheries. (2) environment, and (3) recreation. The recreation activities, and environmentally sensitive were placed into three resource categories: (f) fisheries, (2) environment, and (3) recreation. The sensitivity of each category to hydrologic changes in the watershed was analyzed. This analysis indicated that although the sensitivity of the various resource areas varied, the areas of highest sensitiviresource areas varied, the areas of highest sensitivi-ty were distributed throughout the watershed. The areas of highest sensitivity for fisheries and envi-ronmental resources were primarily located in the upper watershed and central portions of the water-shed where development is not as concentrated.

Recreational areas exhibited the highest sensitivity Recreational areas exhibited the fighest sensitivity in the lower watershed where development is intense. The analysis of potential impacts of development on hydrologic regime, and in turn on flooding, erosion, base flows and environmental impacts, indicated that the impacts are interrelated. The requirements for storm water management The requirements for storm water management must consider all of the areas of impact investigated. Control of peak flow rates is required to avoid flood damage impacts, volume control is needed to mitigate erosion impacts, recharge is needed to avoid base flow reduction, and water quality control is needed for environmental concerns. MANAGING TRANSBOUNDARY WATER DI-VERSIONS: EXPERIENCE FROM A PRIVATE

Hackensack Water Co., Harrington Park, NJ. Research and Development Div P. C. Tao.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 429-438, 4 fig,

Descriptors: \*Diversion structures, \*Interbasin transfers, \*New Jersey, \*Water resources management, Hackensack River Basin, Reservoir operation, Reservoirs, Wanaque Reservoir.

The four-reservoir system in the Hackens The four-reservoir system in the Hackensack River basin is the main source of supply for the Hackensack Water Company (HWC) in New Jersey. Lake DeForest, the largest among the 4 reservoirs, is located in Rockland County, New York, the head water of the Hackensack River. The Spring Valley Water Company (SVWC), a sister utility serving Rockland County, also relies on Lake DeForest as its primary source for meeting its summer water. Rockland County, also relies on Lake DeForest as its primary source for meeting its summer water demand. Wanaque South Project is an interbasin water diversion project, capable of pumping up to 75 million gallons per day from the Wanaque Reservoir system in the Passaic River Basin to Hackensack. The Wanaque South Project is a joint venture between HWC and North Jersey District Water Supply Commission (NJDWSC). The NJDWSC, a New Jersey State water supply agent, provides wholesale water to the municipalities in Passaic and Essex Counties, New Jersey. This paper presents: (1) the regional water supply concept to manage the Lake DeForest release across the New York-New Jersey State boundary and settle the dispute between New York (SVWC) and New Jersey (HWC) on the operation of Lake DeForest during a drought; and (2) the reservoir storage and interbasin water transfer strategy to manage diversion across the franchise lines and manage diversion across the franchise lines and watershed boundaries, and to optimize the water supply resources for HWC and NJDWSC. DECISION SUPPORT SYSTEM FOR WATER TRANSFER EVALUATION.
Nebraska Univ.-Lincoln. Dept. of Civil Engineer-

J. Stansbury, W. Woldt, I. Bogardi, and A. Bleed. Water Resources Research WRERAQ, Vol. 27, No. 4, p 443-451, April 1991. 6 fig, 3 tab, 21 ref.

Descriptors: \*Decision making, \*Management planning, \*Water demand, \*Water transfer, Agriculture, Case studies, Competing use, Environmental impact, Geographical information systems, Groundwater, Nebraska, Platte River, Regional analysis, Surface water, Water supply.

As the United States has changed from a young water economy to a mature one, there has been greater competition among water users (e.g., irrigators and municipalities) and more complex problems for water managers. A decision support system (DSS) was developed to help decision makers analyze the economic, social, and ecologi-cal ramifications of water transfers. Such a DSS is needed because the United States is evolving from needed because the United States is evolving from a development-oriented water economy to a more complex one that emphasizes conservation and reallocation (i.e., transfers). The DSS consists of three main modules: (1) a conjunctive surface-ground water model, (2) an impact analysis segment, which uses a geographic information system (GIS) that integrates model output with information from the study area to estimated economic, social, and ecological impacts, and (3) a multicriteria decision making algorithm that ranks the transfer schemes based on trade-offs of indicators which are assembled into a hierarchical structure. Ten different water transfer alternatives were extendible of the state of the which are assembled into a hierarchical structure. Ten different water transfer alternatives were examined in a case study to demonstrate the applica-tion of the proposed DSs. The study area consist-ed of Gosper, Phelps, and Kearney Counties in south-central Nebraska. The area is an agricultural region having significant groundwater reserves in the Ogalalla and similar aquifers. The major stream in the study area is the Platte River. It was found that the DSS can be a valuable aid for water managers because it: forces consideration of a wide range of impacts; allows complex technical inforrange or impacts; allows complex tecnmical intor-mation to be incorporated into the decision making process; users readily available personal comput-ers; employs GIS to facilitate analysis and interpre-tation of the results; uses accessible and easily understood weighting systems that establish confi-dence and facilitate sensitivity analysis; and, pro-vides final trade-off analysis in graphical form. ster-PTT)

## DO WE HAVE A NATIONAL WATER POLICY.

Journal of Soil and Water Conservation JSWCA3, Vol. 46, No. 1, p 14-16, January/February 1991.

Descriptors: \*Public policy, \*Water policy, \*Water resources development, \*Water resources management, Federal government, Mississippi River, State governments, Tennessee Valley Authority, Water law, Water rights.

The national water policy is basically a reactive policy that has evolved in response to problems after they have arisen. Under the Constitution, the first reaction to water-related problems was to leave the responsibilities for their solution to the states and their inhabitants. The National Commission Waterways was established in 1910 to coordinate. sion Waterways was established in 1910 to coordinate policies of the water resources agencies with the USDA. A permanent Waterways Commission, the Newlands Commission, was authorized in 1917 to coordinate the work of the agencies, but it was never appointed. Instead, the Federal Power commission was formed in 1920. With the enactment of the Boulder Canyon Project Act in 1927 and the expansion of the Mississippi River and Tributaries Project in 1928, the pace of multiple-purpose water resources development substantially increased. It was not until the passage of the Tennessee Valley Authority Act in 1933 that a coordinated water resources policy received legislative recognition, but then only for the Tennessee Valiver Basin. Nuresources policy received legislative recognition, but then only for the Tennessee River Basin. Numerous other programs went on the books, but failed to be effective. In the meantime, water pollution control programs grew to dominate the water resources management field, with massive federal grant programs of up to 75% of the costs of publicly owned water treatment plants. Because of the history of the evolution of national water policy, water resources policy has always dominated land use policy in federal programs. Thus, many of the problems stem from the fact that land use policy has been handled by nonfederal governpolicy has been handled by nonfederal govern-ments and water policy has been primarily federal. For the future, water professionals, working with professionals in other resource management fields, are the ones who will have to develop policies that can be used to turn the system toward the long-term goal of conjunctive management of all natural resources. #### WATER FUTURES.

Agricultural Research Service, Fort Collins, CO. J. van Schilfgaarde. Journal of Soil and Water Conservation JSWCA3, Vol. 46, No. 1, p 17-19, January/February 1991. 2

Descriptors: \*Water policy, \*Water resources development, \*Water resources management, \*Wet-lands, Agriculture, California, Florida, Muck soils, Public policy, Water quality.

Water development has been crucial to the development of the U.S.. Draining of wetlands has opened up much land for agriculture. The period of American history when wetlands were mercilessly drained for farming and human inhabitation reflected a development ethos to conquer the land, to harness the water. This developmental ethos became a fundamental tenet of American culture. Development of water resources has served the nation well. The production of vegetables on the muck soils in southern Florida would be impossible without water development, as would farming in the Imperial Valley and the Central Valley in California. The country has suffered a tremendous loss of wetlands, however; some 90% of wetlands loss of wetnands, nowever; some 90% of wetnands are gone. Development has also led to loss of wild rivers, plant and animal species and degradation of water quality and other components of the ecosystem. Changes are beginning to occur. They are driven by the public and are slowly being endorsed by Congress and by state legislatures. There is now a move from an era dominated by development ethos into one dominated by an environmental ethic. A new, redrafted federal policy based on scarcity, not abundance is needed. The nuts and bolts of a new agenda would include a review of water policy that truly reflects the cost of service. It would also include a reevaluation of the subsidy system, so there is a consistency in federal policies between Agriculture and Interior. Industrial leaders seem to be able to see no further than their quarterly balance sheets. And when it comes to natural resources, there is a tendency to look no further than the next election. A longer view is necessary. (Mertz-PTT) W91-10506

#### CRITICAL AREA PROGRAM OF MARYLAND: IS IT CLEANING UP THE CHESAPEAKE BAY. Chesapeake Bay Critical Area Commission, Annapolis, MD.

S. J. Taylor. In: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 19-25, 10 ref.

Descriptors: \*Chesapeake Bay, \*Land use, \*Legal aspects, \*Maryland, \*Water pollution control, \*Water resources management, Decision making, Local governments, Pennsylvania, Regulations, State jurisdiction, Virginia

The Critical Area Protection Program for Mary-land's part of the Chesapeake Bay marked the first success for a State-mandated land use/growth management program. Premises, practice, and pre-scriptions played an important role in this success. The Critical Area Law improves coordination in two ways. First it sets up a vertical decision making structure for the development process, to ensure that landowners' actions are consistent with the stated goals of the law. Second, the Critical Area Law establishes a commission to monitor and regulate actions of local and state authorities. As a result of this program, which began in 1984, the Commonwealth of Virginia and Pennsylvania have Commonwealth of Virginia and reasons removed initiated land use/growth management programs of their own. In addition, Maryland is examining growth pressures and land use changes occurring in the rest of the state not subject to the Critical Area Program, with the intent of prescribing a growth management approach for its remaining lands. The effort's success will probably not be known for at least five more years, after the local jurisdictions have had the expe rience of these additional years of implementing their programs. Suc-cess will depend upon the willingness of local jurisdictions, State agencies, and landowners to be stewards of their resources and of their land, and to correct the imbalances in water, sediment, and nutrients flowing in the Bay. ## CHALLENGE OF IMPLEMENTING ECOSYSTEM MANAGEMENT PLANS IN THE GREAT LAKES BASIN.

Michigan Univ., Ann Arbor, School of Natural S. H. MacKenzie.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 69-77, 10 ref.

Descriptors: \*Environmental protection, \*Great Lakes, \*Interstate commissions, \*Water resources management, Ecosystems, Financial aspects, Politi-cal aspects, Public participation, Public policy, Water quality.

In order to maintain and enhance the integrity of the Great Lakes, an ecosystem approach to water resource planning and management should be adopted. The implementation of ecosystem management plans is critically important, yet inordi-nately difficult to achieve. There are six preconditions which are essential to the implementation of ecosystem approach: intergovernmental the ecosystem approach: intergovernmental co-ordination; interdisciplinary cooperation; political support; public participation; funding; and conflict resolution. Intergovernmental coordination and resolution. Intergovernmental coordination and interdisciplinary cooperation are the linchpins of ecosystem planning and management. By achieving these two preconditions, the administrative and programmatic capacity of governments to implement the ecosystem approach may be attained. The political arena struggles with the intricacies of balancing pluralist goals and democratic processes in a complex intergovernmental system. Disparate values and interests clash continually in an effort to dominate multic policy. The political arena is the values and interests clash continually in an effort to dominate public policy. The political arena is dy-namic and uncertain. Ecosystem planning and management is trying to find its niche within this institutional maze. The odds may well be stacked against widespread adoption of the ecosystem ap-proach, yet ultimately, its implementation may be essential to ecological survival. There are some essential to ecological survival. There are some indications that implementation of the ecosystem approach may be on the horizon in the Great Lakes region. The cause for optimism is found in the Remedial Action Plan (RAP) initiative under the auspices of the International Joint Commission (IJC). Since 1973, the IJC Water Quality Board has identified 42 'Areas of Concern' across the Great Lakes Basin where the quality of a Great Lake or its tributaries has been severely compromised, and extraordinary measures are needed for remediation. The vast majority of these 'hotspots' are located around harbors, connecting channels, and major municipalities. RAP plans are currently being designed to rectify these water quality prob-lems. While the jurisdictions responsible for devising the RAP have considerable latitude, they are expected to incorporate ecosystem concerns an tapetest of incorporate coststant concent and into their planning process. As such, they provide an exceptional means for studying the challenges of implementing the ecosystem approach. (See also W91-11003) (Lantz-PTT) W91-11011

## REVIEW OF INTERBASIN WATER TRANS-FERS WITH SPECIFIC ATTENTION TO BIOTA.

North Dakota State Univ., Fargo. Dept. of Civil

Engineering.
G. Padmanabhan, K. Jensen, and J. A. Leitch. IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 93-99, 23 ref.

Descriptors: \*Biological studies, \*Ecological effects, \*Environmental impact, \*Interbasin transfers, \*Water transfer, Aquatic life, Case studies, Ecosystems, Garrison Diversion Project, Literature review, Monitoring, North Dakot

Although economic aspects of large-scale interba-sin water transfers are of considerable importance, in recent years the biota transfer aspect of the problem has assumed greater importance. Many proposals for water transfers are opposed by the public on the grounds of biota transfer implications. An ecological assessment of large-scale water transfer is complex due to a lack of theory and information on biota transfer. Recognizing this and information on blota transfer. Recognizing this need, a multi-disciplinary research program on biota transfer studies sponsored by the Garrison Diversion Conservancy District and the State Water Commission (North Dakota) was instituted by the North Dakota Water Resources Research Institute. Several aspects of the problem are cur-rently being investigated under this program. One of the first tasks was to review the literature for evidence or lack thereof, of biota transfer in water transfer schemes which are already in place. Much transier schemes which are aiready in piace. Much ilterature is available on economic and technical feasibility studies; but the studies on biota transfer are relatively few. Most of the discussions appear to be philosophical at best, and comprehensive case studies are almost non-existent. This situation exists because: (1) the pre-monitoring and post-

## **Evaluation Process—Group 6B**

monitoring of biota transfer and impacts have to be over long periods of time to draw meaningful conclusions; (2) there are not enough baseline studconclusions, (2) there are not enough baseline studies; and (3) the science of evaluating biota transfer implications is in its infancy. The review clearly brought out the need for both diagnostic monitoring, which permits establishing trends or change in aquatic ecosystems, and prognostic monitoring, which will help predict the biological consequences of these changes or transformations of the quences of these changes or transformations of the ecosystems; the water transfer scheme should be conducted on a regular basis and under a prescribed program. Also, monitoring must continue under the same basis after the interbasin water transfer scheme is implemented to help evaluate the impact and, hence, to formulate remedial measures. RESOLVING CONFLICTS ON THE DANUBE: THE GABCIKOVO-NAGYMAROS POWER DAM PROJECT.
Department of the Interior, Washington, DC.
I. L. Murphy.
IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 139-148, 5 fig, 12 ref

Descriptors: \*Danube River Basin, \*Gabcikovo-Nagymaros Power Dam Project, \*International commissions, \*International waters, \*Water re-sources management, Czechoslovakia, Financial aspects, Hungary, International agreements, Man-agement planning, Model studies, Political aspects.

Past and current decision processes affecting the rast and current decision processes artecting the use of Danube River Basin resources are exemplified by the recent controversy over the Gabcikovo(Bos)-Nagymaros Power Dam Project. For more than a decade it appeared that despite growing opposition from water users in riparian countries, and environmentalists in both east and countries, and environmentains in both east and west, that Czechoslovakia and Hungary would complete the construction of a large hydroelectric system on the Danube River. Hungarian government leaders, increasingly sensitive in this and other issue areas to an aroused electorate, decided other issue areas to an aroused electorate, decided in the late summer of 1989 to suspend its participation in the Bos-Nagymaros project pending environmental studies and constituent surveys. On October 30, 1989, the Hungarian parliament voted to withdraw permanently from the project. The basin is an important, threatened resource for all eight is an important, threatened resource for all eight riparian countries; discussion and negotiations, however, have not yet produced a conflict resolution process that might have prevented or could resolve the present dilemma. The planning, design and construction phases of the project were accomplished by bilateral agreements without a rigorous environmental impact assessment. The latest issue, which has resulted in acrimonious exchanges between the two Fastern European countries and issue, which has resulted in acrimonious exchanges between the two Eastern European countries, and the possibility of severe financial losses to both, has emphasized the need to put in place a decision process which ensures an equitable distribution of a vital, shared resource to all riparian countries. A policy model which has been tested on river basin conflicts elsewhere is used to analyze the current equation of the Danube and to make recommendasituation on the Danube and to make recommendastuation on the Danube and to make recommenda-tions for a permanent Danube-wide resolution process. These recommendations should include: (1) the establishment of a planning task group with membership from the appropriate water bureaus in each of the eight riparian countries and their for-eign ministries; (2) an agreement between the ripareign ministries; (2) an agreement between the riparian countries about a reporting deadline for a subgroup which would address information system needs; (3) discussion of the need for an integrated planning function and its proposed parameters—it should vote a budget and suggest activities for the next two years; and (4) the appointment of a subgroup of experts to assist with the resolution of the Bos-Nagymaros conflict. (See also W91-11003) (Lantz-PTT) W91-11018

FLUCTUATING WATER LEVELS IN THE GREAT LAKES-ST. LAWRENCE RIVER BASIN: AN EVALUATION FRAMEWORK FOR THE ANALYSIS OF POTENTIAL ACTIONS.

Corps of Engineers, Buffalo, NY. Buffalo District. J. W. Karsten, and C. N. Meeder. IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 229-239, 3 fig. 1 tab, 7 ref.

Descriptors: \*Fluctuations, \*Great Lakes, \*Great Lakes/St Lawrence River Basin, \*International Joint Commission, \*Water level, \*Water resources management, Data interpretation, Decision making, Economic aspects, Management planning, Political aspects, Social aspects.

The development and testing of an evaluation framework has been one of several significant activities undertaken within the International Joint Commission (IJC) Reference study on fluctuating water levels in the Great Lakes-St. Lawrence River basin. The evaluation process provides for an ongoing analytical capability for use by govern-ments and others. It consists of the following comments and others. It consists of the following com-ponents: (1) an inventory of existing and potential problems related to fluctuating water levels and their extremes; (2) an inventory of over 100 alter-native courses of action, classified into six types of measures; (3) an impacts matrix identifying possible impacts of measures on affected interest groups, including the natural environment; (4) selection and definition of six evaluative core criteria and 22 associated operational criteria; (5) assessment of measures through an evaluation instrument; and (6) measures through an evaluation must unless, and (y) compiling findings on alternative courses of action. The evaluation framework has demonstrated usefulness in organizing and structuring the process of conducting an evaluation and in docum lts. It does not remove the necessity of having to make technical judgements and value judgements in assessing the necessity of having to make technical judgements and value judgements in assessing uncertainties regarding economic, social, environmental, and political matters. It is a mechanism which requires the rendering of such judgements explicit. (See also W91-11003) (Author's abstract) W91-11026

FLUCTUATING WATER LEVELS: AN ISSUE MANAGEMENT APPROACH.

Guelph Univ. (Ontario). Dept. of Geography. B. Smit, and C. J. Stewart.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 299-307, 1 fig. 7 sef.

Descriptors: \*Decision making, \*Fluctuations, \*Great Lakes, \*Water level, \*Water resources management, Institutional constraints, Public policy, Resources management.

The Great Lakes provide a wide variety of services to interests in the basin. These services can be affected by fluctuating water levels. If expectations for gain from the services are not met, the affected parties may petition governments to act. These problems and their solutions are bounded by a complex and dynamic social, political and physical setting affecting the appropriateness of traditional benefit-cost approaches to evaluating potential actions. The conventional approach has been criticized for the narrow ranse of critieria examined, its cized for the narrow range of criteria examined, its reliance on judgements external to the affected parties, and a lack of public input. An alternative approach is offered in which no judgement is made approach is offered in which no judgement is made regarding the degree of adverse consequences suffered by an interest. Rather, the positions taken by the interests are examined for their underlying factual understanding and their relation to the responsibilities of governments. This focus on the impetus for petitioning facilitates the identification of government actions to effectively manage the issue. (See also W91-11003) (Author's abstract)

WATER DIVERSION FROM THE GREAT LAKES AS A DYNAMIC GAME. Minnesota Univ., St. Paul. Dept. of Agricultural

Engineering. N. Becker, ar

N. Becker, and K. W. Easter.
IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 495-505, 6 tab, 19 ref. NOAA Grant No. NA86AA-0-SG112.

Descriptors: \*Decision making, \*Game theory, \*Great Lakes, \*International waters, \*Water resources management, Canada, Political aspects, Social aspects, United States, Water management.

The five Great Lakes can be classified common property or open access resource. This is a consequence of the lack of a well-defined system of property rights governing water use in the lakes. Decisions by interested parties are interconnected, since withdrawing water from one point may affect water levels in the entire system. This, in turn, can adversely affect hydropower production and commercial navigation. Contributing to the complexity of the problem are the eight U.S. states, two Canadian provinces and two federal governments. Game theory is implemented to describe this situation-several games are constructed to dethis situation-several games are constructed to de-scribe different market structures. Of particular interest is the number of players that participate in the game, as well as the expectations which they hold. Open-loop (where players commit them-selves to future actions) and closed-loop (where players do not commit themselves to future ac-tions) are compared for the ten players game (eight states and two provinces), two players game (U.S. usins) are compared for the ten players game (eight states and two provinces), two players game (U.S. versus Canada) and one player game (a social planner's solution). It is shown that trying to solve an open-loop game ignores part of the externalities involved, and thus can underestimate the social loss involved in these lakes. RED RIVER BASIN GRASS ROOTS POLICY

I. Yohe.

IN: Agrichemicals and Groundwater Protection:
Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. 259-264.

Descriptors: \*Decision making, \*Nonpoint pollution sources, \*Policy making, \*Project planning, \*Public policy, \*Red River Basin, Education, Evaluation, Geographic information systems, Land use, Organizations, Water quality control, Water

The Red River basin is a geographic area of 111,000 square miles and covers parts of Minneso-ta, North and South Dakota, Manitoba, and Saskatchewan. Residents of the basin feel the pressure to somehow affect the future directions of policy and decision making in order to deal with the land and water problems that exist in the basin. Involving basin residents, educating them on issues, and providing opportunities for cooperation are key components in implementing plans and solving these problems. In 1979, this grassroots involvement saw the development of the International Coalition for Land and Water Stewardship in the Red River Basin (TIC). The TIC has initiated many activities that in some manner relate to education or cooperation of basin residents to enhance their participation in the policy process. In addition, the TIC has sponsored several International Land and Water Summit Conferences where a consensus building process is used. The process enables participants to decide together an issue of priority and actions that can deal with the issues. This partnership role can be seen in the Comprehensive Local Water Planning project (CLWP) which brings together data (information) and the consensus process to enable local grassroots citizens and leaders to become enual partners with the cation or cooperation of basin residents to enhance zens and leaders to become equal partners with the state and others in planning and preparing for the future in land and water resource policy and deci-sion making. SOCIO-ECONOMIC IMPACT OF IMPROVED WELLS IN RURAL SIERRA LEONE, Njala Univ. Coll., Freetown (Sierra Leone). Dept. Naia Univ. Coli., Freetown (Sierra Leone). Dept. of Environmental Studies and Geography.

O. M. Bah, G. E. Hollis, and P. Richards.
Journal of the Institution of Water and Environmental Management JIWMEZ, Vol. 5, No. 1, p 36-42, February 1991. 1 fig, 10 tab, 6 ref.

Descriptors: \*Developing countries, \*Project planning, \*Sierra Leone, \*Water supply development, \*Wells, Benefits, Future planning, Rural areas, Social aspects.

The use and benefits of the improved wells con-structed with the participation of the local commu-nities in rural Sierra Leone was examined through nities in rural Sierra Leone was examined through data obtained from questionnaires in four sample villages. Interviews with well users and quantitative monitoring of water abstraction were also used to assess patterns of well use. Only 36% of the improved wells were operational in the dry season, and these made a modest contribution to water demand in the villages. Half the water consumption was on the remote farms where improved wells played a negligible role. Social and cultural difficulties with the wells caused reduced use of these improved water supply sources. Postuse of these improved water supply sources. Post-project evaluation by a multi-disciplinary team could provide invaluable inputs to the planning of future water supply development schemes in de-veloping countries. (Geiger-PTT) W91-11358

MANAGING WATER RESOURCES IN LATIN

Economic Commission for Latin America and the Caribbean, Santiago (Chile).

Natural Resources Journal NRJOAB, Vol. 30, No. 3, p 581-607, 1990, 5 fig, 2 tab.

Descriptors: \*Flow control, \*Political aspects, \*Regional development, \*Regulated flow, \*South America, \*Water resources management, Argentina, Chile, Colombia, Control systems, Evaluation, Irrigation programs, Latin America, Legal aspects, Peru, Water law, Water policy, Water supply development, Water use efficiency

Investment in water control projects has formed a major part of efforts to achieve economic development in Latin America over the last four decades. The result has been an increase in the regulation and control of rivers so that even the largest river systems are subject to considerable interference in their natural flow regimes. The expansion of con-trol works has raised the need to weigh the social trol works has raised the need to weigh the social question of managing complex water systems rather than operating individual control works directed towards satisfying the demands of specific uses. The nature of water management in Latin America was evaluated by examining four case studies of contemporary water management practices: (1) Irrigation in the Province of Mendoza, Argentina: (2) Water management and regional Argentina; (2) Water management and regional development in the Bogata River Valley, Columbia; (3) The Tinajones irrigation project, Lambayeque, Feru; and (4) Water management in the valley of the River Limari, Chile. The case studies show that despite some advances, the present state of water management is far from optimum. Many water management is lar from opinium. Many issues inherent to water system operation are being poorly handled and even ignored. Too commonly, the evidence from the case studies indicates that management actions have magnified rather than reduced the influence of unfavorable external con-ditions, neither have they responded to available opportunities. In general, the management institu-tions in the case studies do not demonstrate a dynamic style of management. Among all the technical, financial, and political problems encountered in the case studies, the need to achieve and maintain a high standard of management seems to be the most urgent. DEVELOPMENT

WALESPIED DEVELOPMENT IN ASIA: STRATEGIES AND TECHNOLOGIES.
World Bank Technical Paper No. 127. World Bank Publications, Washington, DC. 1990. 227p.
Edited by John B. Doolette and William B. Ma-

Descriptors: \*Asia, \*Literature review, \*Management planning, \*Water resources management, \*Watershed management, Agricultural engineering, Crop production, Developing countries, Erosion, Land tenure, Land use, Research priorities,

A review of watershed development issues arose A review of watersited uperconducting sauce arose from the realization that a number of current and planned World Bank-supported projects in the Asia region deal with the linkages between upland productivity and environmental conditions and productivity and environmental conditions and are, in various ways, motivated by concern with downstream impacts such as flooding and sedimen-tation. High priority was attached to identifying discrete operational problems that could be better understood from review of existing data and analysis. In addition, the review was aimed at providing overall guidance to the Bank's dialogue with boroveran guidance of the Jank's unangement.

Working papers on six issues of direct operational concern were initiated, to be conducted by World Bank staff and consultants in the context of ongoing operations. These working papers, presented as

## Cost Allocation, Cost Sharing, Pricing/Repayment—Group 6C

chapters in the report, illustrate methodological approaches to project analysis, summarize the state of the art on solutions to technical problems and discuss institutional and social processes that bear heavily on the viability of watershed management projects. In addition to the research and operationwork that has gone into the working papers, a colloquium on watershed management was held at the World Bank in October 1988. Experts from research organizations and other agencies presented results of their work on a number of topics, including the impact of erosion on crop yields, sedimentation processes, and the impact of land tenure on development investments. FRAMEWORK FOR PLANNING, MONITOR-ING, AND EVALUATING WATERSHED CON-SERVATION PROJECTS.

SERVATION PROBLETS.

G. S. Morgan, and R. C. Ng.

IN: Watershed Development in Asia: Strategies and Technologies. World Bank Technical Paper No. 127. World Bank Publications, Washington, DC. 1990. p 159-171, 1 ref.

Descriptors: \*Asia, \*Management planning, \*Project planning, \*Water resources management, \*Watershed management, Developing countries, Environmental policy, Evaluation, Land use, Monitoring, Multiobjective planning, Watersheds.

Watershed planning, monitoring, and evaluation (PME) tasks are frequently cited as among the most important components of successful projects. Nevertheless, the potential of PME activities will be achieved only if it is clearly understood who is to use the results and for what purposes and if the practical limitations of available methodologies and techniques are accepted. In general, there is agreement that monitoring and measurement of physical processes (crosion, deforestation) or physical delivery of project inputs is easier than measuring the less tangible, people-centered goals of watershed rehabilitation programs such as increasuring the less tangible, people-centered goals of watershed rehabilitation programs such as increasing beneficiary participation. In designing the PME components of watershed projects, the mutually reinforcing nature of these tasks must be clearly understood. The functional tasks that must be addressed by the staff responsible for implementing the PME components include: technical records the PME components include: technical records management, geography and cartography, village-level information management, watershed strategic planning, formulation of site-development plans and annual work program, monitoring progress; monitoring results, monitoring benefits, interiproject evaluations, evaluation of impact of physical treatments, and report generation (internal/ external). PME methodologies and procedures need to be flexible and well adapted to local circumstances. Due to the wide variation in objectives, scale and scope of investments in watershed projects, there can be no blueprint which is universally applicable or acceptable in all situations. In all situations, PME must be seen as an evolutionary process, building slowly on existing capabilities over relatively long time periods. This is particularly important when monitoring the effects of project investment on the productivity of natural systems such as forests, soils, or water. (See also W91-11563) (Fish-PTT)

Descriptors: \*Economic aspects, \*Water conserva-tion, \*Water resources management, \*Watersheds, Financing, Land use, Ontario, Recreation.

An assessment of the watershed-based conserva-An assessment of the watersned-oased conserva-tion programs requires a review of the techniques applied and the implementing agency. The conser-vation movement in Ontario was established in the early 1920s. Current annual expenditures of the 38 early 1920s. Current annual expenditures of the 38 Conservation Authorities on water and related land management, recreation, conservation education and administration totals 396 million. An example, the Saugeen Valley Conservation Authority, received up to 75% of its annual budget of \$2.2 million from provincial grants, the rest from program funds and local revenues. Through past conservation programs, Ontario has invested, over the past 40 years, close to \$1 billion in water control structures alone. Although these past watershed-based conservation programs provided great tangible and intangible benefits, the current review of Conservation Authority programs identified the one and mangione benefits, the current review of Conservation Authority programs identified the need of clear water and related land policies, ac-companied by increased funding. COSTS AND BENEFITS OF MOVING TO PEAK-LOAD PRICING FOR MUNICIPALLY-SUPPLIED WATER.

Brock Univ., St. Catharines (Ontario). Dept. of Economics.

In: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 453-461, 1

Descriptors: \*Cost-benefit analysis, \*Costs, \*Pricing, \*Water supply, British Columbia, Canada, Case studies, Economic aspects, Utilities, Vancouver. Water demand. Water resources management.

The pricing practices currently used by most North American water utilities are inefficient be-cause they do not reflect marginal costs. Further-more, the philosophy underlying the setting of the philosophy underlying the setting of is concerned more with cost recovery than prices is concerned more with cost recovery than signalling resource scarcity. An alternative ap-proach is to set prices to maximize the consumer's surplus net of supply costs. This leads to marginal cost pricing, and any factor affecting marginal costs may be incorporated into the pricing formucosts may be incorporated into the pricing formu-la. The efficiency gains arising from the move to marginal cost pricing may be outweighed, howev-er, by the costs of implementation if universal metering is required. A case study is examined; the costs of service and demand for water for the Vancouver Works are characterized statisti-cally. Costs are a function of input prices and quantities and the level of output. Demand is a function of price income and a vector of social quantities and the level of output. Demand is a function of price, income, and a vector of socio-conomic variables. A computer program simulates the move to marginal cost pricing (and its variant under cyclical demands, peak-load pricing) and computes costs and benefits. In several cases, the net benefits are positive. (See also W91-11003) (Author's abstract) W91-11047

INDUSTRIAL WATER PRICING FOR ONTAR-IO: TOWARDS REALISTIC PRICING.

Inland Waters Directorate, Ottawa (Ontario).
D. Tate, and R. Rivers.
IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 463-473, 4

Descriptors: \*Ontario, \*Pricing, \*Water resources management, \*Water supply, Canada, Costs, Economic aspects, Federal jurisdiction, Utilities, Water

Realistic water pricing is put forth in Canada's Federal Water Policy as one of five central strate-

gies for future water management. A system of two-part tariffs was suggested as being the most effective form of pricing, both for municipal water and for industrial water services. For industries and for industrial water services. For industries deriving their supplies from municipal systems, the fixed part of the tariff would be based on the share of fixed cost of each industry, while the part which varies with volume used would be based on the marginal cost of supplying water plus an extra strength sewer use charge. For self-supplied industries, a portion of the industrial water price would tries, a portion of the industrial water price would be designed to cover the costs of provincial and federal water management. A preliminary and quite rough example of the suggested system shows that, based on annual water management costs in Ontario of \$429 million, the water charge costs in Ornario of 3429 million, the water charge per cubic meter, prorated over the province's total industrial water use, would be \$0.18. Such a charge, if levied, could result in a 30% drop in industrial water intake and a 25% drop in consumption. (See also W91-11003) (Author's ab-W91-11048

WATER RATE STRUCTURE FOR DEMAND MANAGEMENT IN THE REGIONAL MUNICI-PALITY OF WATERLOO.

Triton Environmental Consultants Ltd., Burnaby (British Columbia).

(Orlins Columba). R. H. Tufgar, M. R. Follett, and B. A. Benninger. IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 475-484, 1 fig.

Descriptors: \*Water demand, \*Water rates, \*Water resources management, \*Water supply, Cost-benefit analysis, Costs, Economic aspects, Management planning, Model studies, Ontario, Waterloo.

The Regional Municipality of Waterloo, Ontario, reached a crisis period during the summer periods of 1988 and 1989 when demands for water, at times, reached or exceeded the capacity of high times, reached or exceeded the capacity of high growth with a fixed groundwater supply source. Plans are in place for additional source capacity, however, these facilities will not be in place until 1991. The Region has recognized the potential dangers of a relatively fixed water source comdangers of a realitively intended water source combined with an increasing demand, through growth, for a number of years. In the mid-1970s, a progressive water conservation program was developed to control water demands. In 1988 the Region initiated a water and sewage rate study to meet two objectives. First, the rate structure was to identify water supply costs, assign the costs to relevant categories and ensure that the revenue matched these costs. Second, the rate structure was to assist with demand management. The rate study met these objectives by identifying relevant cost categories, assessing the system demand structure by gories, assessing the system demand structure by consumer class and peaking characteristics, and developing a rate model that provides a structure to promote water demand management. The basis of the model is: that the cost/revenue balance reflects a user-pay approach; the accounting procedure follows American Water Works Association procedures; the base-extra capacity approach is used to reflect the peaking characteristics of the water system in the rates; that a component to capture the cost of long-term capital planning is included to help ensure smoother rates; and, that the rate structure reflects differences in consumer menueu to nep ensure smoother rates; and, that the rate structure reflects differences in consumer groups. Components from the areas available such as administration, regulation, education and operations management must be combined for an effective demand management program. ## Field 6—WATER RESOURCES PLANNING

## Group 6C—Cost Allocation, Cost Sharing, Pricing/Repayment

Descriptors: \*Cost-benefit analysis, \*Irrigation programs, \*Irrigation water, \*Pricing, \*Saskatchewan, Agriculture, Alfalfa, Crop yield, Potatoes.

It is the present water policy of the Saskatchewan government to subsidize irrigation water to farmers. Consistent with federal government guidelines, an analysis was made of the expected imports, if farmers were charged, so that the costs of water development (plus the operating and maintenance development (plus the operating and maintenance of water delivery system for irrigation) are covered. Impacts of such a price level were estimated on various size farms and crops grown under irrigation. Data on prices, costs, yields and water costs were obtained from secondary sources. Increased water charges adversely affected returns for most irrigation crops, with the exception of protectors. For allelie, sources the exception of protectors. potatoes. For alfalfa, returns were significantly reduced. Similarly, center pivot irrigation was affected the most, particularly that on small irrigated farms. Descriptors: \*Drinking water, \*Massachusetts, \*Water costs, \*Water quality, Economic aspects, Social aspects, Trichloroethylene, Utilities, Water quality control.

Historically, water has been a cheap, abundant resource in the northeastern United States. This perception is being challenged by increasing demands from a growing population, and a decreasing supply resulting from contamination. This has forced a reassessment of the value of clean, safe water supplies. One way to estimate the worth of water is to measure the dollar amount people are prepared to spend on protecting the sources of supply. In the summer of 1989, a contingent valuation survey of four towns in Massachusetts was conducted to assess willingness-to-pay (WTP) for increased protection of their water supplies. All the towns in the study rely on groundwater for the public drinking water supply and two have experipublic drinking water supply and two have experi-enced contamination from trichloroethylene (TCE). The data indicate that there may be some significant differences in WTP for water supply protection based on local environmental condi-tions. The experience of a contamination incident appears to lead to higher valuations of a safe supply of water. At the present stage however, it is not clear whether this is the case. The issue is confounded as those who have experienced a con-tamination incident tend to view their water suptamination incident tend to view their water sup-plies as being less safe and thus may be prepared to pay more to reach the highest safety level. The analysis of WTP by safety level indicates a de-creasing WTP for more protection as perceived safety increases. (See also W91-11003) (Lantz-PTT) W91-11056

Integrated Pest Management (IPM) is a system of agricultural pest management which makes use of every available technique to control pests to a level below that which causes economic injury, in a manner which is least harmful to human health and the environment. The implementation of IPM programs in New York State emphasizes demonstration, education and transfer of financial responsibility to the private sector. Transfer of programs sibility to the private sector. Transfer of programs to the private sector allows for a larger audience to be addressed yet presents several challenges in the development of a program. Involving the private sector in the management and decision making process from the outset is essential. Growers need to take the responsibility to help design IPM processes which meet their needs and are valuable. grams which meet their needs and are valuable to them, if they are going to eventually pay for them. There is a continuous need for dialogue and data There is a continuous need for dialogue and data exchange between the public and private institutions both before and after financial responsibility has been transferred. Although many challenges remain to be met, IPM programs in New York State have been and continue to be transferred to private funding. (See also W91-11162) (Korn-PTT) W91-11180

## 6D. Water Demand

WATER MANAGEMENT ISSUES FOR THE

Florida Univ., Gainesville. Coll. of Engineering. W. Viessman. Water Resources Bulletin WARBAQ, Vol. 26, No. 6, p 883-891, December 1990. 1 tab, 19 ref.

Descriptors: \*Evaluation, \*Future planning, \*Water demand, \*Water management, \*Water policy, \*Water quality, \*Water resources institutes, \*Water resources management, \*Water supply, Environmental protec-tion, Land use, Nonstructural alternatives, Regional analysis, Regional planning, Water allocation, Water issues, Water law, Water resources develop-

Water management includes applying structural and non-structural measures to problems related to water supply, water allocation, water quality, ex-treme events, and environmental protection. Needed are innovative approaches to problem solving, non-traditional coalitions for addressing regional issues, objective forums, foresight caparegional issues, objective forums, foresignt capa-bilities, and institutional reforms. The need for water management institutional reform is widely recognized, but the key to accomplishing it is hard to find. Support for change can be kindled and justified by analyzing and displaying the payoffs that could be achieved through alternative ways of solving problems and managing system. However, solving problems and managing systems. However, better coordination among planning and management agencies and greater consistency among plans, regulations, and actions remains a problem. The Administration and the Congress have taken the view that the states should assume a greater

portion of the national water management budget. However, some aspect of managing the nation's waters will require a sustained federal effort. The states should be provided some federal aid and guidance in the form of new financing options and professional cadres equipped to carry out expanded assignments. In addition, policies for land and water management should be consistent and coordinated. Finally, water policies of the future must take on a more global dimension. Few contemporary problems are local in nature. More emtemporary problems are local in nature. More emphasis must be placed on regional planning and management, and regional institutions to accommanagement, and regional institutions to accom-modate this must be devised. Unless the water policies of the future reflect a more holistic view, there will be little chance of staving off a water crisis of major proportions. (Korn-PTT) W91-10807

#### WATER USE REDUCTIONS FROM RETRO-FITTING INDOOR WATER FIXTURES

Brown and Caldwell, Pleasant Hill, CA. J. B. Whitcomb.

Water Resources Bulletin WARBAQ, Vol. 26, No. 6, p 921-926, December 1990. 1 fig, 3 tab, 4 ref.

Descriptors: \*Domestic water, \*Model studies, \*Plumbing, \*Water conservation, \*Water use, \*Water use, \*Statistical analysis, Uncertainty, Water demand, Water fixture retrofitting, Water supply, Water use modeling.

Water supply planners are using estimates of po-tential water savings from installation of water conserving devices to design retrofit programs throughout the country. However, a fair amount of uncertainty exists in these water saving esti-mates. The primary reason for the uncertainty is that water savings change as household water use characteristics, both technological and demographic in nature, change. A water use model was devel-oped to estimate water savings from the installa-tion of low-flow showerheads and toilet displacement devices in residential housing. The model measured household water use in per capita terms measured nousenoid water use in per capita terms with adjustments for age of occupants, household income, and type of water fixtures. The results of the study revealed that water use reductions from retrofitting indoor water fixtures depend on both technological and demographic characteristics. The occupant's age and income had a pronounced effect on water savings. One consequence of the effect on water savings. One consequence of the study is that it informs water resource planners to be wary of extending a single water savings esti-mate calculated in one region to another. Regional differences in these types of characteristics can significantly affect water savings. In addition, the estimates of water savings can also provide useful information to other water agencies interested in the effectiveness of these types of retrofit devices. (Korn-PTT) W91-10811

Descriptors: \*Data collections, \*Databases, \*Great Lakes, \*Water use, Data interpretation, Data storage and retrieval, Groundwater resources, International agreements, Interstate compacts, Surface water, Water demand, Water resources management, Water supply.

In 1987, the Great Lakes Regional Water Use Data Base Repository was established at the Great Lakes Commission by an international Great Lakes Water Resources Management Committee. During its second year of operation, the repository has worked closely with water management experts from throughout the region to refine reporting requirements and measurement techniques to better represent annual water withdrawals and consumption in the Great Lakes Basin. The database catalogs water withdrawal and consumption in nine active categories of use for ten jurisdictions and six subbasins by three types of withdrawal (groundwater, Great Lakes surface water and tributary streams or other surface water). Reports of ways and are becoming more refined and useful in regional planning and estimation as jurisdictions move toward full compliance with data input requirements. The future utility of the database will be enhanced as the individual jurisdictions continue their efforts to improve estimation techniques, measure rather than estimate water withdrawals, and establish standard and timely data collection and reporting programs. Continued state and provincial interest and involvement in refining and expanding the database is desirable to ensure that the database and repository continue to support jurisdictional needs and other ongoing Charter initiatives in the future. WILL FREE TRADE DRINK CANADA DRY. Department of the Environment, Ottawa (Ontario). Inland Waters Directorate.

In: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 383-392, 1 fig, 2 tab, 15 ref.

Descriptors: \*Canada, \*Free trade, \*International agreements, \*Legislation, \*Water resources management, \*Water supply, Hydroelectric power, Regulations, Social aspects, Water resources.

During the great national debate in 1988 over free trade with the United States, some critics in Canada charged that water resources would be subject to the terms of the proposed trade agreement. The response of the Government of Canada was first to deny the charge, then to accelerate legislation banning large-scale water export. Analysis of the opposing positions and of related events is inconclusive at this time. For the next few years, however, there appears to be too much opposition in Canada and too little interest in the United States for continental water marketing to be taken seriously. But Canada's water resources may be implicated by the Free Trade Agreement in another way than diversion of lakes or rivers across the international boundary. Rather than commit water for export, some provinces are exploring the economic rewards of building water projects for the generation of electricity which would be committed entirely for export. This would have the effect of tying up northern water systems for long periods in advance of domestic needs and in spite of abundant evidence of environmental and social disruptions caused by existing hydroelectric development. WATER MARKET IN THE SOUTHERN FRONT RANGE OF COLORADO.

Colorado Coll., Colorado Springs. Dept. of Economics and Business.

M. G. Smith.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 535-542, 1 fig, 13 ref.

Descriptors: \*Colorado, \*Water demand, \*Water resources management, \*Water rights, \*Water transfer, Agriculture, Competing use, Domestic water, Legal aspects, Water supply, Water use.

Water markets have existed in Colorado for some time; farmers within the same mutual ditch company have rented and traded water between themselves for over 80 yrs. What is new in the last 20 yrs is the entry of cities into the water market to purchase agricultural water for transfer into municipal, commercial and industrial uses. The result of these sales is the wholesale reallocation of water away from agriculture to the cities and from one region to another. Who the buyers are for any particular water right is largely determined by a city's ability to capture, store and convey the water to its customers. While Denver is the largest city along the Front Range of Colorado, with the most extensive conveyance and storage system, it has been one of the least active players in the water market over the last 20 yrs. The two most active players in the water market have been the cities of Aurora and Thornton. Aurora takes water from the Arkansas River through the pipeline that is jointly owned with Colorado Springs, while Thornton has gone north to purchase water from the Cache la Poudre River and west for rights on Clear Creek. Golden, Arvada and Westminster are also purchasing water rights on Clear Creek. Colorado Springs can capture water from Fountain Creek and directly from the Arkansas. The city has purchased water rights from both Twin Lakes and the Colorado Canal Company on the Arkansas. Water rights have a number of attributes that determine their value in the market. These are: priority date, adjudication date, source, location and type of use. Two principle types of sales make up the major water transfers from farmers to the cities within the region: water right transfers and shares in mutual ditch companies. A water rights transfer is the sale of a water right from one party to another. Shares in mutual ditch companies were originally founded to manage the irrigation ditches withdraw from farming or ranching they are free to sell their shares. Anyone is free to buy these shares as long as they can demonstr

Increased economic activity has created problems in management of the Lake Onega-Svir River water resources complex (Soviet Union). Increased water consumption (particularly nonreturnable water consumption) and intrabasin water redistribution are occurring. In the future, interregional redistribution of water may be needed to solve the

water supply problem. Lake Onega and a 97-km stretch of the Svir' River, including the Ivinskii floodplain, constitutes a single reservoir of the Upper Svir' hydroelectric station. A study was undertaken to determine the water balance of the reservoir of the Upper Svir' hydroelectric station using data covering the 31-yr period of operation from 1953/54 to 1983/84. Two activities are of particular importance on this system: water transport and hydroelectric power generation. The outcome was examined of two variants of runoff from Lake Onega: 3.5 and 7.5 cu km/yr. Discharges were determined as probability curves for these two scenarios. The annual generation of electricity by hydrostations of the Svir' cascade could decrease by 18% with withdrawals of 3.5 cu km/yr and by as much as 36% with withdrawals of 3.5 cu km/yr and by as much end of the installed capacity of the hydrostations of the Svir' River is guaranteed only in the winter. In the summer the interests of the hydropower industry are slighted to provide for water transport needs. (Rochester-PTT)

Students in a senior-level water supply course at the University of Central Florida were required in order to account for all personal water use over a 24-hour day) to compare student demands with values reported in the literature. The accounting was done by successive classes over 8 years, totaling 252 students. The average use was 93.6 gal/capita/dgpcd), within the figures found in the literature. The observed range was 74.2 gpcd to 143.3 gpcd. The latter value was apparently an anomaly, because it was far outside the other seven averages, which ranged from 74.2 to 96.2 gpcd. Overall average percentages for use of waste disposal for the eight classes were somewhat different from published values. Food service and laundry use percentages were reasonably close to published values. On a probability plot, the anomaly of the 143.3 gpcd point stands out immediately, the remaining seven values producing a straight line. From the plot, the mean was 89 gpcd, with a standard deviation of 13 gpcd. For a one-in-100 probability, the values were 59 gpcd and 119 gpcd. (Doria-PTT)

NEGOTIATION TECHNIQUES TO RESOLVE WESTERN WATER DISPUTES.

National Ecology Research Center, Fort Collins,

B. L. Lamb, and J. G. Taylor. Water Resources Bulletin WARBAQ, Vol. 26, No. 6, p 967-975, December 1990. 1 fig, 33 ref.

Descriptors: \*Legal aspects, \*Negotiations, \*Resource allocation, \*Water allocation, \*Water law, \*Water rights, Bargaining, Conflict resolution, Instream flow, Problem solving, Public participation, Water resource management.

Every water resource negotiation has its own special characteristics. The first thing to be avoided is the temptation to apply a mechanistic process to dynamic, value-oriented problem solving. Using a simple model of negotiation misses many opportunities for improved outcomes. More fruitful negotiations are possible when one recognizes the rich complexity of water rights disputes expressed in competitive, cooperative, and integrative bargain-ing. Even though the competitive strategy is the most common starting place, it can be shown that, under most circumstances, disputes can be much more productively resolved if approaches evolve more productively resolved if approaches evolve toward cooperative or innovative strategies. One key to productivity is recognizing the strategy that dominates bargaining. The history of a dispute, as well as the record of opponents' behavior, are both excellent guides for identifying strategy. Success is achieved when the parties move beyond mere mechanical attempts to use tactics and progress

toward mutual problem-solving. The ability to do
this is conditioned by the number of parties involved, the mixture and disparity of values held,
attentiveness of various publics, the presence of a
strong third party, and the participants' abilities to
evaluate and use technical information. Understanding all these factors must be covaled with standing all these factors must be coupled with skill in identifying the real needs of the parties involved. (Korn-PTT) W91-10817

TRANSFERABILITY OF WATER ENTITLE-MENTS IN AUSTRALIA. University of New England, Armidale (Australia). Centre for Water Policy Research. J. J. Pigram, and W. F. Musgrave. Regulated Rivers Research & Management RRMEP, Vol. 5, No. 5, p 391-399, November/ December 1990. 2 tab, 25 ref.

Descriptors: \*Australia, \*Local governments, \*Water demand, \*Water entitlements, \*Water management, \*Water rights, Industrial water, Irrigation water, Legal aspects, Urban areas, Water esources, Water use.

Until recently, entitlements to water in Australia have been tied to a specific area of land. Several State water management agencies have now adopted more flexible arrangements for the transfer of water rights between users on regulated streams.
The case of freer transfers is linked to the per-ceived need for greater efficiency in water use.
Transferability also has potential in facilitating the movement of water between different sectors of the water industry and in achieving more rational and environmentally acceptable use of resources. Justification for breaking the nexus between water rights and land needs to be assessed against a number of physical, social, economic, and environmental issues some of which have only become apparent with accelerated resource development, and expansion and concentration of Australia's urban-industrial base. These trends are reflected in urban-industrial base. These trends are reflected in competing claims on water resources to supply the increasing demand from city-based populations; to maintain the viability of industrial systems; to sustain more intensive high technology forms of irrigation agriculture; and to satisfy the water needs of often remote mining and tourist developments. No longer can such claims easily be met by harnessing further water resources. Transfers of water rights, on a much larger scale, within and between wateron a much larger scale, within and between waterusing regions and sectors, and across State borders, are likely to be an important element in Australia's water industry in coming decades. INTERNATIONAL AND TRANSBOUNDARY WATER RESOURCES ISSUES.

Proceedings of the Symposium held April 1-4, 1990, Toronto, Ontario. American Water Resources Association, Bethesda, Maryland, 1990. 652p. Edited by John E. FitzGibbon.

Descriptors: \*International agreements, \*Interna-tional waters, \*Water resources management, Great Lakes, Great Lakes/St Lawrence River Basin, Interstate commissions, Legal aspects, Re-sources management, Water resources develop-ment Water supply. ment, Water supply.

The symposium provided an opportunity for the American Water Resources Association and the Canadian Water Resources Association to bring together the water resource issues and concerns together the water resource issues and concerns that are shared by the peoples of North America. These interests are shared both in terms of management of the drainage systems that span the common borders, and in the sense of shared issues and problems within the two nations (Canada and the United States). The operations and successes and failures of regional water resource organizations formed two special sections focusing on the organizations that deal with water resource management problems. It provides a prospective on the various approaches to water resource management and highlights the outcomes of some of these ap-proaches. The second theme of the symposium is that of transboundary water. Transboundary

waters represent an important area of concern not only in terms of the Canadian-United States boundary, but for any water body which is within more than one jurisdiction. The management of these than one jurisdiction. The management of these resources requires a commitment to the common good on the part of all jurisdictions and thus a coordination of approaches, agencies and programs. The third theme deals with the Great Lakes and St. Lawrence--the major shared drainage system between Canada and the United States. The size of this system and its importance to the large concentrations of population that depend on them makes the management of the Great Lakes a key on-going issue. The papers in these proceedings provide a comprehensive view of the current status of management of the Great Lakes. The fourth theme is one that is shared by all water managers, that is the problem of determining the fourth theme is one that is shared by all water managers, that is the problem of determining the value of water resources. The problem of pricing and valuation of this common property is seen as a key to effective management of water resource use. The challenge outlined in the papers is the search for an appropriate means of determining the value of water and how to charge for it. The fifth theme is that of the history of Canada and the United States water resources policy and manage-United States water resources policy and management. The final themes relate to several major problems which are of critical importance to the management of water. These include the impact of climatic change on water resources, the management of groundwater and water quality management. (See W91-11004 thru W91-11065) (Lantz-W91-11003

GREAT LAKES CHARTER: POTENTIAL AND REALITY

New York State Public Services Commission, Albany. H. G. Williams.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 1-9, 6 ref.

Descriptors: \*Great Lakes, \*Great Lakes Charter, \*International agreements, \*Water resources management, Canada, Databases, Decision making, International commissions, Public policy, United States Water use

The Great Lakes Charter, adopted by the Great Lakes governors and premiers in 1985, commits the governors and premiers to manage the water resources of the Great Lakes Basin cooperatively and in accordance with a watershed management strategy that reflects the unity of the Great Lakes system. The Charter includes an action program to provide better information for future water man-agement decisions. The key feature of this action item is a committee to oversee the development of a common database on Great Lakes water use and a basin water management program to provide a policy and decision making framework for the states and provinces. The Charter encourages sup-port for research regarding flows and lake levels required to protect Great Lakes water resources. The process established by the Charter has resulted in measurable progress in the development of a in measurable progress in the development of a strategy to manage diversions and consumptive uses of Great Lakes water resources, but essential actions remain to be taken by the states and prov-inces before the Charter's potential is fully real-ized. sources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 27-34, 7 ref.

Descriptors: \*Decision making, \*Model studies, \*Water law, \*Water resources management, Management planning, Standards.

Theoretical development of interest representation has been stalled by an inability to clarify the role of such key concepts as power and justice, especially for resource issues affecting multiple publics. The individual context of each situation minimizes the individual context of each situation minimizes the utility of normative models and leaves the issue of a general theory up in the air. Dispute resolution conforms to this mould. Circumstance, history and local conditions restrict the viability of manuals and deterministic models seeking to outline various means for the resolution of conflict. In a practical sense, a well developed, detailed schematic model for negotiated approach to water management is both unwarranted and unverifiable. The Stakeholder Model, which combines philosophy, goals, and strategic planning, is intended as a conceptual guideline for the implementation of a negotiated approach in the provision of interest representation in decision making. The model not only lacks any pretense of theory but, because implementation is site specific, it also lacks specifics regarding procedure. (See also W91-11003) (Lantz-PTT)

LEGAL REGIMES FOR INTERSTATE WATER ALLOCATION IN THE WESTERN UNITED STATES: SOME SUCCESSES AND FAILURES. Mexico Univ., Albuquerque. School of Law C. T. DuMars.

In: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 35-46.

Descriptors: \*Colorado River Basin, \*Interstate compacts, \*Legal aspects, \*Water allocation, \*Water law, \*Water securces management, \*Water supply, Competing use, Decision making, Pecos River Compact, Upper Colorado River

The Colorado River Compact, the Upper Colorado River Compact, and the Pecos River Compact are explored. The Colorado River Compact provides a classic example of intentional deferral of vides a classic example of intentional deferral of difficult legal problems. The Upper Colorado River Compact is an example of a compact which has worked well because of a fundamental need of has worked well because of a fundamental need of the States to cooperate. The Pecos River Compact is an example of a compact which did not leave the problems to future generations, but created prob-lems due to both bad engineering and an unwork-able-decision making structure. There are certain provisions which are destined to provide litigation in the future. For example, where a compact does not make provision for some majority vote, as in the case of the Pecos River Compact. Or, as in the case of the Colorado Compact, where the delivery. case of the Colorado Compact, where the delivery obligation is fixed by a flat quantity of water and the sources of that water are not clearly defined. Likewise, as in the case of the Pecos River Compact, where depletion actions of the upstream user are prohibited with the goal of making more water are prohibited with the goal of making more water available to the downstream user problems are inevitable if the compact is unclear. Finally, a settlement that does not provide all of the negotiatsettlement that does not provide all of the negotiat-ing states with the financial capacity to utilize their share of the water spells trouble. The simple reality is that if one entity benefits by using its water and by ensuring that its counterpart does not use its water, conflict is inevitable. The interstate compact is an excellent political tool. These compacts have drawn the overall contours of the allocation of water in many rivers in the Western United States, but interstate management problems in many cases have not been solved—they are just beginning. INTERSTATE COOPERATION IN DEALING WITH GROWTH RELATED WATER QUALITY IMPACTS ON THE CHESAPEAKE BAY. Rogers, Golden and Halpern, Inc., Philadelphia, B. F. Golden.

IN: International and Transboundary Water Resources Issues. American Water Resources Asso ciation, Bethesda, Maryland, 1990. p 49-56.

Descriptors: \*Chesapeake Bay, \*Environmental effects, \*Environmental protection, \*Interstate compacts, \*Urbanization, Conservation, District of Columbia, Education, Financial aspects, Interstate commissions, Land use, Maryland, Pennsylvania, Population growth, Regulations, Taxes, Virginia.

Population growth, Regulations, Taxes, Virginia.

Chesapeake Bay is influenced largely by three States-Pennsylvania, Maryland, and Virginia-albeit in different ways. These three jurisdictions, plus the District of Columbia, the US EPA, and the Chesapeake Bay Commission constitute the Chesapeake Executive Council. In an historic and unique agreement, these jurisdictions have agreed to reduce the impacts each creates on the Bay and its tributaries. A key component of this effort will be a rationalization of land development practices throughout the watershed. A 12-member panel was appointed to examine the issues of population growth and development in the Chesapeake watershed to the year 2020. The panel established seven visions' of how the projected 2.6 million new residents should be accommodated. These are: (1) development is concentrated in suitable areas; (2) sensitive areas are protected; (3) growth is directed e areas are protected; (3) growth is dire to existing population centers in rural areas rce areas are protected; (4) stewardship of the nd the land is a universal ethic; (5) conservabay and the and is a university conserva-tion of resources, including a reduction in resource consumption, is forced practiced throughout the region; and (6) funding mechanisms are in place to achieve all other visions. Each vision has a series of implementing "actions", including: establish fedof implementing actions, including: establish re-eral, state and local buffer zone programs that require adequate deep-rooted vegetated buffers be left undeveloped around sensitive resources and along all watercourses and water bodies; state and along all water-courses and water bodies; state and local governments must protect water supply watersheds from development; state agencies should establish written environmental stewardship policies to guide their actions and should review their programs to ensure conformance within these policies; states should develop a required school curriculum unit focused on environmental and growth cies; states should develop a required school curriculum unit focused on environmental and growth issues; states should make best environmental management practices mandatory for development, agriculture, and forestry; develop revenue sharing or pooling arrangements among municipalities or counties affected by growth; and, states should encourage development of local taxing districts to allow local governments to recover the operating costs of public facilities unique to that district. The quantification of impacts from these densities led he panel to conclude that the States must take a pivotal role in land use management, or all the technical approaches to improving Bay water quality would be overwhelmed simply by growth. APPLYING SUSTAINABLE DEVELOPMENT TO THE GREAT LAKES-EXPERIENCE AND OPPORTUNITIES UNDER THE BOUNDARY WATERS TREATY.

International Joint Commission-United States and Canada, Ottawa (Ontario).

G. Thornburn.

G. Inornourn.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 149-158, 6 ref.

Descriptors: \*Boundary Waters Treaty, \*Great Lakes, \*Institutional constraints, \*International agreements, \*Sustainable development, \*Water resources development, Hydroelectric powerplants, Nonpoint source pollution.

A review of the practice and experience of the International Joint Commission under the Boundary Waters Treaty provides many examples as to how the concepts of sustainable development can be and have in fact been applied. The reasons for an early interest in these concepts include the very process by which the Commission ensured that all affected interests were taken into account in deciaffected interests were taken into account in decision-making, an approach that inevitably lead to a tracing of a wide range of impacts both directly and indirectly through environmental linkages. Examples are drawn from the 75-yr history of the Commission within the Great Lakes region. Specific recent examples include the Commission's approach to the redevelopment of hydro-power facilities at Sault Ste. Marie, the assessment of diversions and consumptive uses of Great Lakes water nonpoint pollution, and the Remedial Action Plans (RAPs) under the Great Lakes Water Quality Agreement. Opportunities for applying sustainable development principles can be found, especially in the RAPs that jurisdictions are required to submit under this agreement. Specific geographic areas that fail to meet the objectives of the Agreement, where such failure has caused or is likely to cause the impairment of beneficial uses or the area's ability to support wildlife, are to be designatarea's ability to support wildlife, are to be designated as 'Areas of Concern'. RAP that embody 'a systematic and comprehensive ecosystem approach to restoring and protecting beneficial uses' are to be prepared for these areas. The investment being put into the RAPs provides Governments and indiput into the RAPs provides Governments and indi-vidual communities with a substantial base for moving forward into the future. There has been real achievement in bringing people together to address common problems across the usual agency, level of government, topical, environmental media, disciplinary, business-government and other insti-tutional barriers. In December 1986, a provincial shoreline management program was established with the Ministry of Natural Resources being named the lead ministry responsible for overall program administration and conservation authorities the lead implementing agency where they exist. The key components of agency where they exist. The key components on the program include the preparation of a policy statement identifying shoreline hazards as a matter of provincial interest, hazard mapping, plan input and review, increased public information and edu-cation initiatives, emergency response funding to provide technical advisory services during the

## Field 6—WATER RESOURCES PLANNING

## Group 6E-Water Law and Institutions

high water period and the preparation of shoreline management plans. In August 1987, the Conservation Authorities and Water Management Branch of the Ministry of Natural Resources produced and circulated Guidelines to assist the local implementing agencies in preparing Shoreline Management Plans. The major goals of a Shoreline Management Plan were defined as minimizing danger to life and property from flooding pression and associated property from flooding, erosion and associated hazards along the shorelines of the Great Lakes-St. Lawrence River system, and to ensure that shoreline development adequately addresses flooding and erosion hazards through a combination of public and private management and development and erosion hazards through a commination of public and private management and development alternatives. The Guidelines for Developing Great Lakes Shoreline Management Plans, in general, have provided sound overall direction to local implementing agencies in the preparation of shore-line management plans. Despite the broad nature of the planning process identified, the Guidelines have been developed in such a manner so as to provide sufficient flexibility to recognize unique or specific shoreline characteristics. Strengthening specific shoreline characteristics. Strengthening the Guidelines through periodic revisions in rethe Cuucines through periodic revisions in re-sponse to shifts in policy direction, advances in technical knowledge and understanding of coastal processes, and changes in legislative and adminis-trative implementation mechanisms will ensure the continued viability and utility of all Shoreline Management Plans. sources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 309-318, 33

Descriptors: \*Decision making, \*Government supports, \*Great Lakes, \*Institutional constraints, \*Water resources management, Canada, Public policy, Resources management, United States.

Government action begins from a base of current policy which reflects it's evolution over time. Policy reflects the government viewpoint, sets

goals and sets constraints on government action and responsibility. Several main themes may be discerned (explicitly and implicitly) in U.S. and Canadian federal water management policy. Gov-ernments seek to promote informed and responsi-ble decision making by interests and to assure resiliency of interests to natural hazards. Governresiliency of interests to natural hazards. Governments also promote economic development, bounded by environmental protection, and seek a planning process giving multiple interests access to the decision making process. These broad policy themes serve to define the nature and scope of government responsibility. In making generalizations about positions of government (i.e. policy), liberties of interpretation are unavoidable and the interties of interpretation are unavoidable and the presence of exceptions must be acknowledged. Indeed, it is the exceptions which demonstrate the main policy themes. Thus, for example, the resist-ance of governments to expanding post disaster aid (despite its existence) and the increased insistence on cost recovery (in the US) for hazard reduction projects (despite a policy of less than full cost recovery), demonstrate the policy presumption in favor of informed and responsible decision making. Acknowledging these limits on the ability to gener-alize, there remain key themes of policy which must be recognized in describing the position of governments. WATERSHED YEARS AT NIAGARA FALLS: CANADIAN AND AMERICAN POLICY RE-SPONSES TO NEW MEANINGS OF POWER, 1905-1914.

California Univ., Santa Barbara. Dept. of History. G. Evans.

IN: International and Transboundary Water Re-sources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 349-357, 33

Descriptors: \*International agreements, \*Interna-tional waters, \*Niagara Falls, \*Public policy, \*Water resources management, Burton Act, Canada, Legislation, Ontario Hydro Commission, Social aspects, United States.

At the opening of the twentieth century, Niagara Falls became a grand amphitheater where dynamic cultural, economic, and political forces all converged. For generations a cultural icon and source of spiritual inspiration, Niagara became a stage setting for one of North America's earliest and most intense battles over the use and preservation of Niagara's valued resources of power. On both sides of the United States-Canadian border, corporate leaders, public officials, and concerned citizens debated the question of who should control and benefit from the Falls' multiple meanings of power. In response to separate but equally vigorous popular public crusades in the United States and Canada, the Ontario, government came to exert far greater control than ever before over both the aesthetic and utilitarian resources of power at Ni-agara. Passage of the 1906 Burton Act and legislation creating the Ontario Hydro Commission in 1906 testify to the new involvement of government in formulating public policies to manage the flow

of water over the Falls. (See also W91-11003) (Author's abstract) W91-11038

MILK RIVER: HISTORICAL TRANSITIONS IN AN INTERNATIONAL WATERWAY.

Montana State Univ., Bozeman. Water Resources Research Center. M. F. Wolfe.

IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 359-371, 1 fig, 31 ref.

Descriptors: \*Alberta, \*Conflicting use, \*History, \*International waters, \*Milk River, \*Montana, \*Water resources development, \*Water resources management, Canada, Federal jurisdiction, Inter-national agreements, Legislation, Public policy, United States, Water rights.

An examination of the manner in which the United States and Canada settled their respective portions of the Milk River basin, reveals the historical similarities and differences that characterized the delarities and differences that characterized the development of the region on both sides of the 49th parallel. Encouraged by government policies and by two railroads, settlers came into this isolated prairie region and water disputes soon erupted. These disputes provoked two far-reaching decisions: the US Supreme Court's Winters decision in 1908, which granted reserved water rights to the Ft. Belknap tribe; and the Boundary Waters Treaty of 1909, which apportioned the waters of the Milk between Canada and the United States. Since that time, water development in the American portion of the basin has proceeded largely without regard either for undeveloped tribal reserve water rights or for Alberta's undeveloped share of the river. In the face of recurring water shortages in Montana's segment of the river, two native groups and the segment of the river, two native groups and the province of Alberta now plan to develop their unused share of the river. In an attempt to avoid further conflicting use, a number of possible solu-tions have been proposed, but all are founded on assumptions very different from those which gov-erned in the past: a more comprehensive basinwide management scheme and improved water use efficiency. The three phase 'comprehensive plan' proposed to Montana irrigators by state and federal water managers includes: (1) a joint board of control for better basin-wide management; (2) recontrol for better basin-was management; (2) re-habilitation of the irrigation system and improved on-farm irrigation techniques for better water use efficiency; (3) if necessary and politically feasible, a new water diversion from the Missouri River; and (4) a possible rental agreement between state irri-gators and Alberta who has offered to lease storage space in the new reservoir to Montana. After age space in the new reservoir to Montana. After 100 years of shared use of the Milk River, the goal of these plans is to find a way to provide water to all those who are entitled to it. Prior to 1930, the right to use water in the prairie provinces of Alberta, Saskatchewan and Manitoba was administered by the Government of Canada. In 1930, the administration of these rights was nsferred to individual provinces. Because most of the region's major streams flowed across political boundaries, the need for a cooperative approach to water management was required. The Governments of Canada and the three provinces

## WATER RESOURCES PLANNING-Field 6

## Water Law and Institutions—Group 6E

established the Prairie Provinces Water Board by signing the Master Agreement on Apportionment in 1969. This Agreement set out an apportionment formula for the sharing of the natural flow of transboundary waters. The Agreement also established interprovincial water quality management within the Board's mandate. The Board has developed water quality objectives and a monitoring program along the interprovincial boundaries. The Board is also actively involved in interprovincial groundwater management and the maintenance of a water use database. Despite the fact that the Board does not have any legislative basis for enforcing its mandate, it has been successful in the administration of the Master Agreement. While this success can be attributed to a number of factors, the spirit of cooperation which exists among the members of the Board and its committees has proven to be the critical factor. NEW YORK CITY'S DELAWARE RIVER BASIN SUPPLY-A CASE STUDY IN INTER-STATE COOPERATION-.
New York City Bureau of Water Supply.
J. P. Conway, and R. Hurwitz.
IN: International and Transboundary Water Resources Issues. American Water Resources Association, Bethesda, Maryland, 1990. p 439-452.

Descriptors: \*Delaware River Basin, \*Institutions, \*Interstate compacts, \*New York City, \*Water resources management, \*Water supply, Delaware, Interstate commissions, New Jersey, New York, Pennsylvania, Regulations.

The turn of this century saw New York's demand for water increasing rapidly. This was due to large immigration and the merging of Brooklyn, which is across the East River from Manhattan, with New York City. The City decided to solve its water problems by expansion of the system. In 1961, the Delaware River Basin Commission (DRBC) was formed by the Delaware River Basin Compact, approved by the four states (NJ, NY, PA, DE), and enacted into law, this being the first time that an interstate water agreement on the Delaware River was approved by all the states. There were to be five commissioners, four comprising the governors of each basin state, and one presidential appointee, as representative of the Federal interests. In addition, the mayors of the cities of Philadelphia and New York would be advisors to the Commission. In 1978, at the initiative of the Commonwealth of Pennsylvania, the Delaware River Basin Commission adopted a resolution inviting each of the parties to the 1954 Supreme Court Decree to enter into serious, good daith discussions to establish the arrangement, procedures and criteria for management of the waters of the Delaware Basin. Fourteen recommendations were made which could be grouped into four major categories: (1) drought management; (2) new projects; (3) providing for, and managing, new demands; and (4) identifying and correcting existing problems. The recommendations were adopted by the Commission, after public hearing. Current-

ly, the main source of supply for the City is surface water impounded in three separate upland reservoir systems: the Croton, the Catskill, and the Delaware. The combined systems include 18 storage reservoirs and three controlled lakes having a total capacity of approximately 550 billion gallons. Water is conveyed to the City from the reservoirs in the Croton, Catskill, and Delaware Systems by gravity through large aqueducts and balancing reservoirs. Within the City, water is distributed through two major tunnels and four distribution facilities. (See also W91-11003) (Lantz-PTT)

NONPOINT SOURCES: AGENDA FOR THE

Descriptors: \*Clean Water Act, \*Legal aspects, \*Legislation, \*Nonpoint pollution sources, Federal jurisdiction, Institutions, State jurisdiction, Water pollution sources.

In 1987, Congress shifted from fifteen years of nonpoint source (NPS) pollution planning and problem identification (1972-1987) to a new National NPS action program. The Act placed special emphasis on NPS by moving the provision from Title II (Grants for Construction of Treatment Works) into Title III (Standards and Enforcement), and by strengthening the basic Declaration of Goals and Policy in 101(a) of the Clean Water Act. The law and its legislative history expressed the intent that Federal and State governments should develop new institutional arrangements and come up with a better division of roles and responsibilities to get the job done. Consistent with 319, States are completing their assessments and management programs, which, after EPA review and approval, will serve as the cornerstone of the National NPS program in the years to come. This National NPS Agenda forms the framework for the National NPS program over the next five years, and will be supplemented by annual EPA work programs that provide additional, detailed information. SOIL CONSERVATION SERVICE AND EXTENSION: COOPERATING TO ENHANCE SERVICES (MES PORTION).
P. J. Borich.

P. J. Borich.

IN: Agrichemicals and Groundwater Protection:
Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 125-128.

Descriptors: \*Administrative agencies, \*Nonpoint pollution sources, \*Soil conservation, \*Water conservation, \*Water resource institutes, Agricultural runoff, Cooperative Extension Service, Education, Groundwater quality, Pesticides, Soil Conservation Service, Water quality, Water quality management.

The United States Department of Agriculture (USDA) Nonpoint Source Water Quality Policy and the USDA Policy for Ground Water Quality established policy to integrate surface and ground-water quality protection and improvement into appropriate programs and activities. The reasons for these policies is the growing national concern about the quality of water. Nonpoint source pollution is a significant problem, and agriculture is a potentially major contributor. A Memorandum of Understanding (MOU) was signed in June 1988 which identified the roles of the Cooperative Extension Service (CES) and the Soil Conservation

Service (SCS) in the Strategy for Implementation of USDA Water Quality Policies. The policies provide background and guidance for agency relations in administering water quality policies. The CES has the major responsibility for public education programs based on research information while the SCS, in cooperation with Conservation Districts, will provide technical assistance for implementing soil and water conservation programs. Specific roles are defined for each agency in each of the following areas: (1) toxic substances (i.e., pesticides, household chemicals, wastewaters and sludges, and landfills); (2) both agricultural and non-agricultural nutrients and organics (e.g., chemical fertilizer management and organics (e.g., chemical fertilizer management and viruses (e.g., animal and human wastes); (4) agricultural and nonagricultural sources of salinity; and, (5) agricultural, silvicultural, and construction sources of sediment. COORDINATING ROLES AND SERVICES: SOIL CONSERVATION SERVICE AND EXTENSION SERVICE,

D. G. Burns

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 129-131.

Descriptors: \*Management planning, \*Nonpoint pollution sources, \*Soil conservation, \*Water conservation, \*Water quality control, Administrative agencies, Federal jurisdiction, Institutions, Interagency cooperation, Local governments, State jurisdiction, Training, Water quality, Water resources institutes.

The process of coordinating the roles and services in the Soil Conservation Service (SCS) and Extension Service (ES) involves three major components. The first component involves the incorporation of nonpoint pollution control into the United States Department of Agriculture (USDA) National Conservation Program (NCP). That program provides guidance to each USDA agency involved in the protection and wise use the United States'soil, water, and related resources. A second component involves the establishment of institutional relationships—relationships among the Federal agencies, relationships within the USDA, and relationships with state and local governments. The SCS is in the process of finalizing an agreement with the Environmental Protection Agency (EPA) which will define the respective roles in agricultural NPS pollution control. SCS technical personnel are on assignment in each of the 10 EPA regions and state water quality agencies. The third component involves activities associated with the Water Quality Action Plan. The plan focuses on two major areas; (1) the development and updating of Field Office Technical Guides (FOTGs) including the incorporation of water quality considerations into conservation practice standards; and (2) the SCS will soon be starting a cooperative effort to identify water quality training needs and the development of training materials to address those needs. The initial emphasis will be on pesticide and nutrient management practices. (See also W91-11171) W91-11171

DYNAMICS OF WATER POLICY. Florida Univ., Gainesville.

W. Viessman.

IN: A 25th Anniversary Collection of Essays by Eminent Members of the American Water Resources Association. AWRA Special Publication No. 89-2. American Water Resources Association, Bethesda, Maryland. 1989. p 41-47.7 ref.

Descriptors: \*Education, \*Federal jurisdiction, \*Political aspects, \*Water policy, \*Water resources development, \*Water resources management, Attitudes, Nonstructural alternatives, Public policy, Water conservation, Water law.

The water policies of the past were mainly development oriented. Today, water policy is focused on how to best manage this precarious resource. Major issues include: providing a national forum; providing regional forums; coordination of water resources place and programs educating the pulse. providing regional forums; coordination of water resources plans and programs; educating the public and decision makers; modernizing institutions and agency roles; paying for water management; blend-ing technology with public policy; defining benefi-cial use; protecting and enhancing the environ-ment; and addressing the problems of the future. Public views on water policy have changed signifi-cantly since the 1960's. Nonstructural management is stressed, new definitions of the beneficial use of water are emerging, and joint considerations of water are emerging, and joint considerations of land and water interactions are becoming more common in land and water resources planning processes. There is a need for effective regional planning and management. Better coordination planning and management. Detter coordination among planning agencies and greater consistency among plans is also a requisite. During the last decade, the Federal Administration and Congress have taken the view that the states should assume a greater portion of the national water management budget. It has not been as clear what the Federal role is to be. Comprehensive water resources plans should become the foundation for water resources coision making. Planning should be proactive, guide water management actions, and drive regulatory programs. The water policies of the future must take on a global dimension. Few contemporary problems are local in nature. More emphasis must be placed on regional planning and management and regional institutions to accommodate this must be devised. LEGISLATIVE IMPLEMENTATION OF INTE-GRATED CATCHMENT MANAGEMENT IN WESTERN AUSTRALIA. Western Australia Univ., Nedlands. Faculty of

Environmental Planning and Law Journal EPLJEX, Vol. 7, No. 3, p 199-208, September 1990. 54 ref.

Descriptors: \*Australia, \*Environmental law, \*Public policy, \*Regulations, \*Water resources management, \*Watershed management, Catchment areas, Decision making, Legal aspects, Planning, Public participation, Water law.

The Western Australian government has defined Integrated Catchment Management (ICM) simply as the coordinated planning, use and management of water, land, vegetation and other natural resources on a river or groundwater catchment basis. Current legislation does not provide a basis for Current legislation does not provide a basis for developing a community approach to ICM, especially in respect to private rural land use. Land use is too complex to be regulated by a comprehensive legal code of management practices, for that reason the regulation of land use is achieved by a planning process which gives legal authority to the planning decisions. This discretionary management control of the property of the planning decisions. planning decisions. In its discretionary management permits flexibility in creating principles applicable to particular places and circumstances. In the Peel Inlet and Harvey Estuary some common law rights and duties have been abrogated by legislation which has resulted in administrative structures which rely on bureaucratic action. There needs to be better definition of the rights and duties of the interested parties and procedures by which those parties may cooperate in making resource planning and management decisions. TENSIONS BETWEEN WATER LEGISLATION AND CUSTOMARY RIGHTS.
Melbourne Univ., Parkville (Australia). Center for

Natural Resources Law.

Natural Resources Journal NRJOAB, Vol. 30, No. 3. p 503-520, 1990.

Descriptors: \*Legal aspects, \*Water law, \*Water management, \*Water resources management, \*Water rights, Environmental policy, Riparian rights, Water policy.

To regard customary law as an impediment to modern, rational water management suggests a dis-tinction between less-developed and more-devel-oped systems of law. However customary law often has rich historical, cultural, religious, and orten has not nistorical, cultural, religious, and social roots. Further, the annoying, inconvenient features of customary law-its dynamism; its symbiotic relationship with the possibility of compensation; its tendency to equate dominion over land with dominion over water-are often present in more developed systems of law. The tension between customary and modern systems arises from tween customary and modern systems arises from their different notions of the private and public domains; their different ideas of ownership and its attributes. The insights of the Bruntland Commis-sion (sustainable development, inter-generational equity etc.) require more developed legal systems to limit and re-define the attributes of property. Notions of communal title, inalienability, trustee-ship, the unity of human kind and nature, of comship, the unity of human kind and nature, of communal not individual authority, and of a balance between personal desires and community obligations, underlie many customary systems. More developed legal systems and economic theorists are often uncomfortable with such notions. With an eye on the future, however, the question should not be how to make customary law conform to modern notions, but vice-versa. (Author's abstract) W91-11383

REGULATION OF INTERBASIN TRANSFERS AND CONSUMPTIVE USES FROM THE GREAT LAKES.

Natural Resources Journal NRJOAB, Vol. 30, No. 3, p 561-579, 1990. 3 tab.

Descriptors: \*Governmental interrelations, \*Great Lakes, \*Interbasin transfers, \*State jurisdiction, \*Water law, \*Water permits, \*Water policy, \*Water resources management, Great Lakes Char-ter, Interstate compacts, Judicial decisions, Lake agement, Water supply development.

The Great Lakes were an open access resource with respect to consumptive water use, prior to the promulgation of the Great Lakes Charter and the Water Resource Development Act of 1986. Concern about the open access nature of the lakes was sparked by the Sporhase v. Nebraska ex rel. Douglas Supreme Court Decision, which limited states' ver to prevent water transfers. The resulting binding Great Lakes Charter recommends a set nontoning Orea. Lakes Catalet recommends a set of management rules enforced through state water permits. However, not all Great Lakes States have implemented the Charter Provisions, and damages associated with lake water withdrawals are generally not accounted for by the permits. Because the charter recommends management by a standard (permits enforce some standard) without setting the standard, evolution towards a basin wide trans-(permits enforce some standard) without setting the standard, evolution towards a basin wide trans-ferable permit system is recommended. Transfera-ble permits would require the definition of a stand-ard but would result in a cost effective means of managing the lakes. (Author's abstract) W91-11384

In 1964, Canada sold its share of the power provided by the Columbia River Treaty to the Unites States. That power called the Canadian Entitlement, has been used by Northwest utilities to helpmeet a steadily increasing demand for electricity. That power will be completely repartiated to Canada by 2003. Unless a new sale is arranged, the Pacific Northwest may have to replace as such as Pacific Northwest may have to replace as much as Pacinic Northwest may have to replace as much as 600 average megawatts of energy, and 1,400 megawatts of capacity. Debate on both sides of the border has already begun as to whether the Cana-dian Entitlement will be resold to the United States. Many potentially contentious issues were not envisioned in 1964. These issues include the mitigation of fish and wildlife in the Pacific Northwest, the expiration of the agreement that coordiwest, the expination of the agreement hat coordinates hydropower operations in the Northwest, and renegotiation of the downstream power benefits made possible by the treaty. The regional calculus with regard to power generation and the importance of environmental factors has changed considerably. Greater access to transmission facili-

The simplicity that permitted the extraordinary 19th century federal and state expansionist programs in the American West has evaporated. The extreme laiseze-faire policies of the past along with federal and state subsidation of free mineral, timber, range and water rights has created complex problems all across the region. The West can no longer continue at the same pace the degradation

and consumption of natural resources. The ecoand consumption of natural resources. The eco-nomic and environmental ramifications of tradi-tional extractive development is obvious: rivers and lakes have evaporated, abandoned and work-ing mines emit toxic metals into aquifers and streams, oil reserves are permanently depleted, and clear-cutting of forests causes irreparable environ-mental harm. Most Westerners today believe that the extractive development of western resources is necessary and desirable but ought to be balanced, prudent, and reasonably stable. Sustainable devel-opment meets the needs of the present without endangering the ability of future generations to endangering the ability of future generations to meet their needs. It does not abuse people or resources. It does not exceed and must maintain the carrying capacity of the resource base. The transition to sustainability does not necessitate the sacrifice of all material comforts for a return to some style of subsistence living. However, it does require reexamination of modern society's habit of reaping the benefits now and postponing the costs. (Feder-PTT) W91-11440

The goal of the federal Water Quality Act of 1987 is to substantially and expeditiously reduce the amount of toxic pollutants being discharged into the nation's waterways. In enacting Section 304(1), Congress intended to encourage states to control toxic discharges to polluted surface waters. Pennsylvania codifies its water quality strategy at 25 PA Code Chapter 16, which specifies the guide-PA Code Chapter 16, which specifies the guide-lines and procedures for developing water quality criteria for toxic substances, and sets forth those criteria that have been established to date. As with the federal law, the Chapter focuses on priority pollutants. Chapter 16 contains guidelines for the development of criteria based on aquatic life and on human health. Aquatic criteria address both acute (short-term) and chronic (long-term) expo-sure to toxic substances and the consequences of such exposure. Human health-based criteria are

divided between threshold and non-threshold-level toxic effects. The area most open to legal challenge is the process by which the various rules and criteria are translated into effluent limitations for discharge permits. Because of manpower limitations and other reasons, the Department of Environmental Resources performs its modeling using ronmental Resources performs its modering using far less field data than any scientist would before making a decision. Thus, any permittee faced with effluent limits that it believes may not be justifiable should examine the analysis that generated those limits. (Doria-PTT) W91-11538

TOXICITY REDUCTION EVALUATIONS (TRE'S) AS A TOOL FOR MEETING EFFLUENT STANDARDS.

J. R. Reed.

Water Pollution Control Association of Pennsylva-nia Magazine, Vol. 24, No. 3, p 46-47, May/June

Descriptors: \*Effluent limitations, \*Regulations, \*Water pollution control, \*Water quality standards, Administrative agencies, Chemical analysis, Cost analysis, Economic aspects, Enforcement, Legal aspects, Legislation, Pennsylvania, Permits, Wastewater treatment. Wastewater treatment.

Federal regulations require that states identify all Federal regulations require that states identify all waters impaired by point sources and develop individual control strategies (ICSs) for those point sources within a specific time frame. One method to control the discharge of toxics is the Toxicity Reduction Evaluation (TRE). When specific chemical or toxicity tests show that a discharge is excessively toxic, the state agency responsible for the permit can require the permitte to take action. the permit can require the permittee to take action to prevent adverse effects on the receiving waters. In evaluating toxics reduction, the Pennsylvania Department of Environmental Resources (DER) Department of Environmental Resources (DER) requires detailed chemical analyses of the effluent as part of a 3-step process to (1) verify the extent of the toxic pollutants in the wastewater; (2) determine their sources; and (3) recommend necessary control and treatment practices to achieve compliance. The TRE may identify a remedial action as simple as 'housekeeping' or a modification of plant operations. On the other hand, for complex facilities with numerous or variable wastestreams, a TRE may involve extensive investigation to identification. TRE may involve extensive investigation to identi-fy the toxic constituents and selection of the most ry the toxic constituents and selection of the most cost-effective treatment or source reduction options. The final aspect of controlling toxics is compliance with scheduling and examination of the antibacksliding regulations designed to force action. TREs will lead to changes in permit regulations as they expand our scientific data base on toxics and new treatment technologies. This report describes the evolution of surface water and groundwater law in Nevada, beginning

## Field 6-WATER RESOURCES PLANNING

## Group 6E—Water Law and Institutions

in 1866 (2 years after statehood), and recounts the problems confronted by the Nevada State Engineers in connection with the development of Nevada's water resources from 1903, when that office was created. The Nevada statutes from statehood in 1864 to 1903 contain only three acts relating to underground water, whereas 20 statutes relating to surface water were enacted during this same time period. These three statutes were enacted in 1879, 1887, and 1901 and provided bounties for the development of artesian water. The early legislatures seemed to construe artesian water as water under free flow. In other words, a well would have to be a flowing well to be classified as an artesian well.

The State of Nevada first took cognizance of un-The State of Nevada first took cognizance of underground water as belonging to the public and subject to appropriation when it enacted a new water law in 1913. The first legislative act relating to the administration of underground water was contained in Chapter 210, Statutes of 1915, and remained in force until repealed by the more detailed groundwater law of 1939, which eliminated the reference to percolating water and made all groundwater, capable of being developed, subject to the appropriation laws of the State. The programs of stream gaging and groundwater studies by the US Geological Survey in cooperation with the Office of State Engineer are discussed from the State perspective. The Carey Act and its application to the reclamation of desert lands in Nevada also is described. (Lantz-PTT) also is described. (Lantz-PTT)

The Salt River Valley Water Users' Association always assumed it was the Salt River Project's right to develop the Verde River, against the wishes of the Verde River Irrigation and Power District. The Salt River Project's diversion works at Granite Reef were built below the confluence of at Granite Reef were built below the confluence of the two rivers which furthered their view that it was an intimate part of the Salt River system. Even though the Reclamation Service had never engineered a storage dam on the Verde for the Project, the Interior Department did withdraw the Verde for public entry for the purpose of creating the Salt River Project, and both the United States and the Association filed for surplus Salt and Varda River water in 1906, one were received to Verde River water in 1906, one year prior to the construction of the Project's Granite Reef Dam in 1907. Even before the Association took over operaintenance of the Salt River Project in 1917, it filed for rights to the Verde's Horseshoe dam site in 1914. The numerous consulting engineers were the most persistent players throughout the Verde's development history; their work framed the issue and gave it definition. Generally, the engineers served the interests of organizations which employed them which may explain the diviwinch employed them which may explain the divi-siveness of opinion among them concerning the viabality of the Verde to support an independent irrigation project. The federal government's role in the outcome of the Verde's development was the most critical; it decided the issue. Therefore, what decided the development of the Verde was not the deterministic of any one projection concert. The determination of any one engineering report. The question was not whether the Verde's hydrologic record showed that there was sufficient water for a certain acceptable number of acres or whether the Assocation 'wasted' over half its water supply. It was not the federal government meeting its obliga-tion to provide water to the Salt River Indiansmeeting Indian water demands in central Arizona meeting indian water demands in central Arizona never took precedence. It was not the Depression which preempted to the issue, causing federal ef-forts to build Bartlett Dam to provide emergency work relief. Nor was it settled by judicial decree, because no party was truly interested in risking their future to a court order. Finally, the Verde's development was not the evenetual or inevitable

product of environmental necessity--the historical necessity of central Arizona's need for an ever necessity of central ATIZONA'S need for an ever increasing water supply. Bartlett Dam was built because the Salt River Valley Water User's Association proved more politically powerful then the Verde River Irrigation and Power District. This report chronicles the Salt River Project through photographs and written historical data. (Lantz-

FLOOD-HAZARD ZONATION IN ARID LANDS.

Geological Survey, Tucson, AZ.
H. W. Hjalmarson.
Transportation Research Record TRREDM, No. 1201, p 1-8, 1988. 15 fig, 1 tab, 13 ref.

Descriptors: \*Arid lands, \*Erosion, \*Flood control, \*Flood plain zoning, \*Sediment transport, Flood frequency, Flood plain management, Flow pattern, Geomorphology, Runoff, Sheet flow, Stream channels.

Potential flood hazard in arid southern and western Arizona stem from different geomorphic and hydrologic characteristics and can be grouped into nydrologic characteristics and can be grouped into zones. The zonation is based on the physical fea-tures of the terrain, the sources of flooding, the expected frequency of flooding, and the expected erosion and sediment deposition. Geomorphology plays an important role in determining flood hazard. Although this fact is common knowledge, structures continue to fail or become less effective. structures continue to fail or become less effective. at least in part because of flood plain management regulations that may not be applicable for some zones. The hazards that commonly plague engi-neering works are the lateral bank erosion in zone 2, the scour of channel beds in zone 1, and the sediment deposition and unpredictable flow paths in zone 4. The zonation is based on distinct geomorphic and hydrologic differences between the zones, but there is some overlap. Zones 2 and 3, for example, can define the hazard of the same land where there is a potential for lateral movement of the banks of channels in zone 1 and also for sheet-flow from local rainfall or from runoff from zones 4 or 5. Alluvial fans have a wide variety of flood characteristics, and thus specific areas can be best described by zones 3, 4, or 5. In general, large areas of fans will exhibit characteristics of a single zone. This general zonation is not intended to replace the detailed engineering definition of hydrologic and geologic characteristics of a particular site of interest. Rather, the zonation of flood hazards can be useful to practicing engineers for the general identification of the type and degree of flood hazard. (Lantz-PTT) W91-11390

#### LAND TENURE ISSUES IN WATERSHED DE-VELOPMENT.

In: Watershed Development in Asia: Strategies and Technologies. World Bank Technical Paper No. 127. World Bank Publications, Washington, DC. 1990. p 131-158, 2 tab, 76 ref, append.

Descriptors: \*Asia, \*Conservation, \*Land tenure, \*Land use, \*Literature review, \*Political aspects, \*Watershed management, Developing countries,

Legal aspects, Population density, Productivity, Soil conservation, Water conservation.

In order to document why tenure is relevant to watershed projects and to provide a conceptual framework for making decisions related to tenurial framework for making decisions related to tenurial issues during project design, a review of the literature has been made regarding land tenure and conservation, as well as a review of relevant projects in China, India, Indonesia, Nepal, the Philippines, and Thailand. Watershed development projects aim at improving the overall productivity, sustainability, and equity of land use in fragile, arable, and nonarable lands. Some of the most familiar land tenure systems in Asia are: water. arable, and nonarable lands. Some of the most familiar land tenure systems in Asia are: water-sheds with relatively stable land tenure systems (Java, Taiwan); watersheds with relatively ancient, state-recognized land tenure systems (Burma, China, India, Nepal); and watersheds in 'frontier' areas (Philippines). Population density is extremely important in determining land use in much of Asia. The data are ambiguous regarding the effect of tenure on adoption rates in ongoing or completed watershed projects and the analysis has been confused by a number of factors, such as quality of the technology packages, subsidies, and lack of knowltechnology packages, subsidies, and lack of knowledge about the land tenure situation in project edge about the land tenure situation in project areas. A significant problem with attempts to evaluate the effects of land tenure is that studies have been too simplistic. Some positive measures that can be included in projects to support land tenure changes or to broaden the range of adoption within existing tenure systems include: providing increased extension support; providing sources of credit; focusing on technologies with quicker and high returns; strengthening local institutions; and providing mediation or legal aid to participants. The World Bank needs to continue to study the relationship between land tenure and the adoption relationship between land tenure and the adoption of soil and water conservation technologies, so that clearer directives can be given to task managers as to what strategies are most productive, sustainable, and equitable in the different Asian settings. ## EGYPTIAN APPROACH TOWARDS APPROPRIATE USE OF COASTAL ZONES ON THE RED SEA

Egyptian Environment Affairs Agency, Cairo. E. E. Eid, and M. A. Fawzi. Marine Pollution Bulletin MPNBAZ, Vol. 23, p 331-337, 1991. 2 fig, 1 tab, 9 ref.

Descriptors: \*Coastal waters, \*Coastal zone management, \*Egypt, \*Red Sea, Corals, Economic aspects, Environmental monitoring, Environmental protection, Gulf of Aqaba, Mangrove trees, Oil spills, Public policy, Shores, Species diversity, Tourism, Water pollution control.

Environmental management and appropriate use of coastal zones is one of the major challenges facing Egypt, as a natural outcome of its strategic geographic location straddling both the Mediterranean and the Red Sea which constitute two of the major enclosed coastal seas in the world. The problem of the protection of the marine environment in the

## Ecologic Impact Of Water Development—Group 6G

Egyptian coastal zones is a primary and serious concern of the Egyptian authorities. As a major tourist and recreation area, due to its ecological and aesthetic value, and as a result of a number of environmental pressures including rapid development and oil pollution, a resource management and development plan for the South Sinai coastal zone area was proposed within an integrated Environ-mental Management Plan of the Egyptian coastal zones along the Red Sea. The Gulf of Aqaba coast has been zoned into tourism development areas, protected areas, and National Parks, which will ensure that representative, economic and biologically important ecosystems are preserved to guarcarry important ecosystems are preserved to guar-antee sustained tourism development in this unique area. Due to the oil pollution on the shoreline of the gulf, which endangers both the high coral species diversity and mangroves, pollution control measures are being implemented at the entrance to the Gulf of Aqaba. IMPACT OF COASTAL DEVELOPMENT ON THE INFRALITIORAL ZONE ALONG THE SOUTHEASTERN MEDITERRANEAN SHORE OF CONTINENTAL FRANCE.

Nice Univ. (France). Marine Environment Lab. A. Meinesz, J. R. Lefevre, and J. M. Astier. Marine Pollution Bulletin MPNBAZ, Vol. 23, p

Descriptors: \*Coastal waters, \*Coastal zone development, \*Coastal zone management, \*Environmental effects, \*France, \*Mediterranean Sea, \*Shores, Artificial beaches, Benthos, Continental shelf, Dikes, Infralittoral zone, Land use, Landfills, Port facilities, Ports, Rocky shores, Shallow water, Species diversity

Numerous waterfront developments built on the sea along the southeastern French Mediterranean coast have resulted in large-scale destruction to the infralitoral zone. A total of 185 development projects, extending over 106 km have been built along the 656 km of rocky shores of the Provence-Alpes-Cote d'Azur region 30.57 sq km have been covered by ports, dikes, land fills, and artificial beaches. Because this region's coast has a very narrow continental shelf (only 314.72 sq km between 0 and -20 m), every construction on the sea significantly reduces the area where the benthic significantly reduces the area where the benthic life is richest in species diversity. Today, a total of 9.7% of the shallow water zone between 0 and -20 m and 14.5% between 0 and -10 m have been irreversibly destroyed by waterfront development.

MODERN ENVIRONMENTAL ASSESSMENT PROCEDURES FOR ENCLOSED SEAS. Waikato Univ., Hamilton (New Zealand). Dept. of Earth Sciences

T. Healey, and K. Harada.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p. 355-361, 1991. 1 fig, 27 ref.

Descriptors: \*Baseline studies, \*Coastal waters, \*Enclosed seas, \*Environmental impact, \*Environmental monitoring, \*Future planning, \*Planning, \*Water resources management, Ecological distribution, Ecosystems, Environmental effects, Hydrodynamics, Inlets, Mathematical models, Model studies, Path of pollutants, Resource utilization, Sedimentation, Water pollution.

Enclosed seas on a world-wide scale are typically characterized by low tidal currents and flushing potential, yet are often centers of high population and, therefore, pollution pressure. Accordingly, recognized environmental assessment procedures are applied. For those examples which have little coordinated data, a full baseline environmental insectionities in peeded to, establish a data base. vestigation is needed to establish a data base against which future change can be measured. An integrated multi-disciplinary approach involves the integrated multi-disciplinary approach mivoves the following components: review of previous work and collation of existing data; bathymetric and geomorphologic evolution, and changes; determination of bottom sediment facies and sediment transport pathways and budgets; investigation of water column and surficial sediment geochemistry

and ecotoxicity; inlet hydraulics, tidal, current and and ecotoxicity; inlet hydraulics, tidal, current and wave climate measurements; investigation of marine biology and ecology, and the patterns of ecological distribution in relation to the sedimento-logic, oceanographic, and pollution parameters; numerical modelling of current hydrodynamics; numerical modelling of water quality and pollution dispersion; numerical modelling of hazards such as tsunamis, storm surge and flooding, and the effect of such events on the enclosed sea hydrodynamics, pollution and sediments; and review of the efficacy of the numerical models in relation to the field and politution and secuments; and review of the efficacy of the numerical models in relation to the field and empirical data. Only by undertaking an integrated, multi-disciplinary study can the best future planning decisions be made for resource utilization and management of the enclosed seas. (Author's abstract) W91-10564

ECOLOGICAL ASSESSMENT OF SEMI-EN-CLOSED MARINE WATER BODIES OF THE ARCHIPELAGO SABANA-CAMAGUEY (CUBA) PRIOR TO TOURISM DEVELOPMENT PRIOR TO PROJECTS.

Instituto de Oceanologia, Havana (Cuba). P. M. Alcolado.

Marine Pollution Bulletin MPNBAZ, Vol. 23, p 375-378, 1991. 2 fig, 7 ref.

Descriptors: \*Coastal zone management, \*Economic development, \*Environmental impact, \*Environmental protection, \*Tourism, \*Water resources management, Benthos, Bridges, Construction, Dam effects, Drought, Ecological effects, Freshwater, Highways, Phytoplankton, Population density, Precipitation, Reservoirs, Salinity, Sediments, Silt, Water exchange, Zooplankton.

The semi-enclosed marine water bodies of the Sabana-Camaguey Archipelago (north of Cuba) are the locations of extensive tourism development projects. Highways and bridges across these water bodies are being planned and constructed to reach and interconnect outer bordering keys. In order to evaluate any possible ecological impact and to elaborate recommendations for avoidance or minielaborate recommendations for avoidance or mini-mization of such impact, a multidisciplinary re-search program was planned. In some areas, high organic matter levels in sediments due to the weak circulation regime, which enhances accumulation processes, and high microbial mineralization rates, impoverish benthic assemblages. In some cases, where salinity reaches very high values, sediments are dominated by silt, or a combination of these are dominated by silt, or a combination of these two factors occur, ecological constraints exist. Phytoplankton and zooplankton show lower concentrations than expected in supposedly fertile semi-enclosed water bodies. Precipitation deficits during many years, combined with damming for fresh water storage, and natural limited exchange between inshore and oceanic water are responsible for observed ecological features. ## Group 6G-Ecologic Impact Of Water Development

SOCIO-POLITICAL ASPECTS OF THE BOS-NAGYMAROS BARRAGE SYSTEM.

Regional Environmental Centre, Budapest (Hungary).
B. Borsos.

International Water Power and Dam Construction IWPCDM, Vol. 43, No. 5, p 57-59, May 1991. 1 fig, 1 tab, 7 ref.

Descriptors: \*Czechoslovakia, \*Dam effects, \*Environmental impact, \*Hungary, Bos-Nagymaros Project, Dams, Danube River, International agreements, Polano study, Političal aspects, Social aspects, Systems analysis, Water resources development.

The Bos-Nagymaros (BNB) project on the Danube River had been under way for some time, but until the late 1980s, no environmental impact assessment was done. In May 1989, Hungary unilaterally suspended all construction work on the Nagymaros cam. Later, work also was suspended at the Dunakiliti site of the Czechosolovia-Hungary Gabci-kovo-Nagymaros scheme (known in Hungary as Bos-Nagymaros or BNB). For almost 2 yr since then, no firm decisions have been taken on the fate then, no firm decisions have been taken on the fate susues raised by this project are: endangerment of both quality and quantity of groundwater supplies; impaired self-purification capacity of the Danube as a result of increased eutrophication; unavoidable deterioration of water quality; unknown geologic and seismic risks associated with the dams; dramatic transformation of the landscape with resulting social impact; and unfavorable economic impacts on activities such as agriculture and forestry. The first full analysis was conducted toward the end of 1989 using the Polano method. The study evaluated six areas: economics, ecology, water quality, politics, technical aspects, and miscellaneous. Three alternatives were considered: (1) completion of the whole system; (2) cancellation of the lower dam, Nagymaros, but completion of the upper part, including Bos and Dunakiliti; and (3) cancel the entire project. Ninety-six different factors were evaluated for each case. The results indicated that the best solution in the long term was cancellation of the whole system; (2) cancellation of the poper part, including Bos and Dunakiliti; and (3) cancel the entire project. Ninety-six different factors were evaluated for each case. The results indicated that the best solution in the long term was cancellation of the whole system; (2) cancellation of the bost observable changes, 16 benefits and 12 unknowns versus 77 unfavorable, 11 neutral, 6 benefits, and 2 unpredictable for case 1). Taking action on the results of the Polano study has been hampered by the ina

URBANIZATION AND URBAN WATER PROB-LEMS IN SOUTHEAST ASIA: A CASE OF UN-SUSTAINABLE DEVELOPMENT.

Descriptors: \*Developing countries, \*Environmental effects, \*Urban development, \*Urban hydrology, \*Water pollution effects, Environmental quality, Flood damage, Population dynamics, Southeast Asia.

The urban water problems in Southeast Asian cities are viewed as the consequences of rapid and uncontrolled urbanization and unsustainable development. The pursuit of economic advancement has conjured a disregard for environmental conservation, which in turn has resulted in water problems of considerable magnitude. Despite the promulgation of laws and setting up of governmental agencies, the control of environmental degradation and enforcement of legislations have been slow due to budget and skilled manpower constraints. Moreover, the existing urban conditions do not allow for environmental improvement unless extensive funds are utilized for major urban improvements such as sewerage works, water supply and waste disposal. These improvements are not likely to happen in the near future. In the long-term, given the ever increasing urbanization and population

growth, the urban water problems in Southeast Asia are expected to escalate rather than attenuate unless serious planning and management are carried out. (Author's abstract) W91-1126.

EFFECT OF HYDROELECTRIC STATIONS ON WATER QUALITY AND DEVELOPMENT OF PHYTOPLANKTON IN THE LOWER POOLS OF RESERVOIRS.

L. A. Sirenko, A. I. Denisova, and M. N. Pakhmova.

Pakimova. Hydrotechnical Construction HYCOAR, Vol. 24, No. 6, p 384-388, December 1991. 6 tab, 16 ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 6, pp. 22-25, June, 1990.

Descriptors: \*Dam effects, \*Hydroelectric plants, \*Limnology, \*Phytoplankton, \*Reservoirs, \*Soviet Union, \*Water quality, Algae, Biomass, Chlorophyta, Cyanophyta, Diatoms, Dinoflagellates, Dissolved oxygen, Hydrogen ion concentration, Photosynthesis.

Hydroelectric stations and their reservoirs have been criticized in recent publications in the Soviet Union. One question that has been raised is whether the lower pool becomes a 'dead' water hazardous for the ecosystem and water consumers. Onsite investigations conducted over the period 1982-1986 in the upper and lower pools of hydroelectric stations at Kiev, Kanev, and Kremenchug shed light on this issue. A monthly check of the biomass of algae generally did not show substantial quantitative differences in number and biomass between the upper and lower pools of reservoirs. No significant differences were noted in the qualitative composition of the phytoplankton in the upper and lower pools of reservoirs. Greens, blue-greens, dinoflagellates, and diatoms, typical representatives of the algal flora of the Dnepr River, were equally represented in the water. Neither the accumulation of dead algal cells and organic materials nor degradation of water quality occurs in lower pools as a result of the operation of turbine units. High photosynthetic activity of the algae in both the upper and lower pool can contain less dissolved oxygen and have a lower pH value, but this does not have a negative effect on indices of water quality and oxidative capacity. (Rochester-PTT)

AVALON LAKES: AN ENVIRONMENTAL OP-PORTUNITY.

A. T. Newman, and P. J. Hawker. Journal of the Institution of Water and Environmental Management JIWMEZ, Vol. 5, No. 1, p 66-71, February 1991. 2 fig. 1 tab, 2 ref.

Descriptors: \*England, \*Environmental effects, \*Marsh management, \*Peat bogs, \*Water supply development, Archaeology, Cost analysis, Lakes, Water quality.

The Avalon Lakes project, a concept to utilize shallow basins left by commercial peat exploitation as water storage reservoirs, was deemed too costly by the Wessex Water Authority which was preparing for privatization of the water industry. The engineering proposals for the project would have the lakes provide both flood alleviation and public water supply reservoirs. Secondary benefits would also accrue in the form of habitat restoration due to a reversal of the progressive decline of groundwater levels, and through opportunities for water-based recreation. To render the water from the lakes potable, a pilot-scale water treatment plant was added to the plans in 1986. Several public interest groups and professional consulting firms were involved in project design and evaluations and to assess the environmental impact of the Avalon Lakes project. Although the project was thought to be the best environmental alternative compared to other projects proposed, the costs of the project were not thought justified compared to the benefits. The marsh area will now be managed by local conservation groups until further plans are proposed. (Geiger-PTT)

TOWARDS MANAGEMENT OF ENVIRON-MENTAL PROBLEMS IN EGYPT.

Massachusetts Univ., Amherst. Dept. of Political Science.
P. M. Haas.

Environmental Conservation EVCNA4, Vol. 17, No. 1, p 45-50, 1990. 1 tab, 24 ref.

Descriptors: \*Egypt, \*Environmental policy, \*Management planning, \*Water pollution control, \*Water pollution prevention, Economic aspects, International agreements, Oil, Pesticides, Population dynamics, Public health, Sewage.

As a poor developing country, Egypt faces a wide variety of pollution problems that are associated with poverty. Widespread environmental problems are becoming acute, water pollution is seen as serious, and many new factories are being built without sufficient pollution controls. Consequently there are real threats to public health and agricultural productivity. Most of Egypt's major environmental problems stem from stretching its limited resource-base in order to accommodate the economic needs of its rapidly growing population. It is often difficult to consider non-quantifiable environmental factors in development planning, especially since Egypt suffers from lack of an integrated or comprehensive framework for conducting either economic planning or environmental policy. Although recent policy shifts are admirable, they are clearly insufficient to manage fully the wide range of environmental problems that now face Egypt Greater effort is demanded for the enforcement of Nile river controls, greater investment in oil reception facilities at ports to limit the amount of oil pumped from tanker's ballasts into the Eastern Mediterraen, reductions in government subsidies which encourage small farmers to use excessive amounts of pesticides, and changes in sewage treatment, industrial and domestic practices which all contribute to pollution. With financial assistance from USAID and USEPA, and at their behest, institutions have been developed, policies and legislation introduced, and budgets allocated, for a variety of forms of environmental protection. Greater amounts of foreign assistance will be required because of Egypt's limited range of financial resources. (Doyle-PTT)

Descriptors: \*Aral Sea, \*Descrification, \*Economic development, \*Irrigation effects, \*Water pollution effects, Agricultural runoff, Ecological effects, Fertilizers, Pesticides, Public health, Saline

The Aral, a large, desert-bound sea in south central Asia, was brought to life by the abundant Amu Darya and Syr Darya rivers, which drain into the Aral Sea basin from tributaries deep in Soviet central Asia and Kazakhstan. But the sea, once comparable to one of the larger Great Lakes in North America, has been shrinking at an alarming rate over the last thirty years. Anthropogenic descriffication is occurring in this region; the sea is drying up as a consequence of the development of irrigated agriculture in the basin. Its river deltas and other natural habitats, the local climate, and the regional hydrology have all been similarly affected. Moreover, these negative ecological changes have been accompanied by grave socioeconomic costs: deteriorating human health, increasing unemployment as resource based economic activity declines, and decreasing production of cotton, rice and other agricultural crops. An irre-

## Data Acquisition—Group 7B

versible ecological catastrophe is fast approaching. Saving the Aral region will require a new attitude and an entirely new approach to economic activity throughout Soviet central Asia. (Author's abstract) W91-11441

GEOMORPHIC, GEOGRAPHIC, AND HYDROGRAPHIC BASIS FOR RESOLVING THE MONO LAKE CONTROVERSY.

Mono Lake, a large, hypersaline water body is situated in the lee of California's Sierra Nevada. situated in the lee of California's Sierra Nevada. Since 1940, when the Los Angeles Department of Water and Power began to divert the tributary streams that feed Mono Lake, the lake surface has dropped 45 feet, lake volume has been halved, and lake salinity has doubled. Dust storms resulting from deflation of newly exposed playa surfaces have increased in intensity, and the spatial dimensions of lacustrine habitats have been reduced. Elands used by nesting sulls have become peninsultands used to the storm of the storm o Islands used by nesting gulls have become peninsuissands used by nesting guits nave become pennisu-las, permitting coyotes to invade and disrupt the rookeries. The relationship between lake behavior and the environmental variables that lie at the center of the controversy are quantified. Resolution of the Mono Lake controversy must take into account the fact that the lake will continue to fluctuate in the future. It is unrealistic to hope that environmental change associated with future lake transgressions can be avoided simply by diverting water southward. Future rises are unavoidable. If water southward. Future rises are unavoidable. If the goal of management is to prevent the lake surface from reaching some critical level, it is necessary to 'poad' that level with a buffer that takes into account the inevitable drawdown that will occur during times of drought. Even under the most controlled conditions, in the future the lake will occupy an elevation interval rather than simply a level. Resolution of the Mono Lake prediction that the surface and the simple assessments. simply a level. Resolution of the Mono Lake pre-dicament must be based not on simple assessments of single lake levels. Rather, land managers must weigh and balance multiple environmental benefits and detriments over ranges of elevations and make decisions that involve sacrificing some resources in order to preserve others. MICROZOOBENTHOS OF THE RIVER JIH-LAVA AFTER THE CONSTRUCTION OF THE DALESICE WATERWORKS.

MALESIAE WALERWORKS, Brno Univ. (Czechoslovakia). Dept. of Biology. V. Opravilova. Limnologica LMNOA8, Vol. 21, No. 1, p 243-250, October 1990. 5 fig. 5 tab, 17 ref.

Descriptors: \*Benthic flora, \*Dam effects, \*Ecological effects, \*Jihlava River, \*Limnology, \*Stream biota, Algae, Biomass, Czechoslovakia, Detritus, Invertebrates, Nematodes, Periphytion, Population dynamics, Protozoa, Reservoirs, Rotifers, Species diversity, Submerged aquatic plants, Water level, Water resources development.

To ascertain the impact of the Dalesice Water-works, changes in microzoobenthos were followed at the Hrubsice station on the Jihlava River, Czechoślovakia. Microzoobenthos were studied in 4 microhabitats: epilithic algal periphyton in the torrentile stretch; detritus on submerged macrovegetation in the torrentile stretch; epilithic algal periphyton near the bank in the fluviatile stretch; and, detritus on macrovegetation near the bank in the fluviatile stretch. Microzoobenthos consisted mainly of the following groups of animals: Rhizo-poda, Ciliophora, Nematoda, Rotatoria, and Tardigrada. Abundance and biomass were studied, with biomass calculated from a volume of 0.1 mL of the sample sediment. Indices of diversity (H') and equitability (E) were also determined. In the last year of research (1985), after the waterworks had been in operation for several years, the following changes in the composition of the macrozoobenthos were found by comparison with the preconstruction situation (1976-1977): the number of construction situation (1976-1977): the number of taxa decreased somewhat (Rhizopoda, Ciliophora, Rotatoria); representation of Metazoa was lower (particularly in Rotatoria); and, the values of the indices of diversity and equitability decreased for all of the microhabitats. It was concluded that the all of the microhabitats. It was concluded that the reservoirs affected the microzoobenthos mainly by a reduction in the supply of detritus, and by deepening the river (effectively raising the water level). The character of the river at the station, which was originally that of the barbel zone, changed to that of the grayling zone. (Author's abstract) W91-11521

UPSTREAM EXTIRPATION OF FOUR MINNOW SPECIES DUE TO DAMMING OF A PRAIRIE STREAM.

PRAIRE STREAM.

Oklahoma Univ., Norman. Dept. of Zoology.

M. R. Winston, C. M. Taylor, and J. Pigg.

Transactions of the American Fisheries Society

TAFSAI, Vol. 120, No. 1, p 98-105, January 1991.

Descriptors: \*Dam effects, \*Fish populations, \*Minnows, \*Prairies, \*Red River, \*Stream biota, Aquatic habitats, Chubs, Drainage area, Oklahoma, Reservoirs, Shiner, Surveys.

A spatially intensive survey in 1989 of 52 sites in the Red River drainage in southwest Oklahoma and surveys in all years from 1978 to 1987 on four sites in the drainage provided evidence that construction of Altus Dam on the North Fork of the Red River caused major changes in fish communi-ty structure in the river above the dam. Pre-im-poundment data on the fish communities were scanty, but the inferences they allowed were similar to those obtained by comparing fish assem-blages in the North Fork above the dam with assemblages elsewhere in the drainage, particularly along Salt Fork, which had similar habitat characalong Salt Fork, which had similar habitat charac-teristics. Twenty-five species were collected in the North Fork above Altus Dam, compared to 33 in the Salt Fork and 34 in the North Fork below the dam. The speckled chub Macrhybopsis aestivalis and the chub shiner Notropis potteri were absent in the North Fork above the dam but fairly common in similar streams elsewhere in the area.
The plains minnow Hybognathus placitus and the Red River shiner N. bairdi were among the most common fish species found in southwest Oklahocommon usar species found in southwest Oklaho-ma, but were not collected above Altus dam in the 1989 survey and were collected only intermittently and in small numbers in the long-term survey. It is speculated that these 2 species have repeatedly been extirpated and reestablished as bait-bucket introductions since the dam was closed. Upstream of the reservoir, the sand shiner N. stramineus and the emerald shiner N. atherinoides replaced the plains minnow and Red River shiner as dominant species. (Author's abstract) W91-11535

HYDROMETRIC DATA COLLECTION AND INTERPRETATION IN THE PRAIRIE PROVINCES AND NORTHWEST TERRITORIES. Environment Canada, Ottawa (Ontario). Water

Environment Canada, Ortawa (Ontano). Water Resources Branch. A. R. Perks, I. S. McLaurin, K. D. Harvey, J. H. Wedel, and B. N. Johnson. Canadian Journal of Civil Engineering CJCEB8, Vol. 18, No. 1, p 58-66, February 1991. 6 fig, 4 tab,

Descriptors: \*Canada, \*Data acquisition, \*Data in-terpretation, \*Network design, \*Stream gaging, Northwest Territories, Prairie Provinces, Runoff, Sediment sampler, Semiarid lands, Surface water data, Water yield.

In the Western and Northern regions of Canada, which covers more than half of the total land area of the country, streamflow and water level data are needed for many essential purposes, often in real time. The needs largely reflect the semi-arid environment and include irrigation, water supply, agricultural drought monitoring and forecasting, water apportionment, water allocation, flood fore-casting and control, hydroelectric power genera-tion, navigation, drainage, and fisheries. A hydro-metric network has been developed, with stations on both regulated and natural streams and coveron both regulated and natural streams and cover-ing large and small drainage basins. There are currently 1485 active streamflow and lake level stations in the region. Data from 1317 discontinued stations are stored in archives. At 106 sites, two-thirds of which are in Alberta, sediment data are thirds of which are in Alberta, sediment data are collected. Sediment data from another 300 discontinued sites are available. The Western and Northern Region includes six of Canada's eight major physiographic regions and three major climatic zones. Accordingly the hydrology of the region varies considerably. The hydrometric data records are the primary indicator of the state (available). varies considerably. The hydrometric data records serve as the primary indicator of the state (availability, distribution, and circulation) of surface water resources in the region at any point in time. The average annual flow is useful in assessing the surface water yield of a basin for water supply, irrigation, and environmental studies. Peak streamflows are used extensively in drainage and flood control activities. Plans for future improvements in the hydrometric network include: better documentation summarized information, and mapping of the hydrometric network include: better documen-tation, summarized information, and mapping of hydrometric stations; screening and assessment of individual station records; regional assessments to examine the representativeness of unregulated sta-tions and provide useful information for users; identification of base requirements for regional hy-drology; and enhanced data and information for general applications. STATISTICAL ANALYSIS OF ERRORS IN ES-TIMATING WET DEPOSITION USING FIVE SURFACE ESTIMATION ALGORITHMS.

Pennsylvania State Univ., University Park. Envi-ronmental Resources Research Inst. J. W. Grimm, and J. A. Lynch.

Atmospheric Environment ATENBP, Vol. 25A, No. 2, p 317-327, 1991. 6 fig. 3 tab, 18 ref. Pennsyl-vania Department of Environmental Resources co-operative Agreements ME81163 and ME86164.

Descriptors: "Acid rain, "Error analysis, "Kriging, "Monitoring, "Nitrates, "Pennsylvania, "Statistical analysis, "Sulfates, Algorithms, Chemistry of precipitation, Hydrogen ion concentration, Mathematical Processing of the Proc

Wet deposition measurements of H(+), SO2(2-) and NO3(-) from 29 monitoring sites located in and around Pennsylvania, were analyzed to quantify errors associated with extrapolating point estimates of deposition using five surface-fitting algorithms. The influence of site density on estimation errors received with seah surface agreement were also associated with each surfacing algorithm was also investigated. The five surfacing algorithms differed little in their abilities to predict the concentration or deposition of individual ions found in precipitation in Pennsylvania. However, the size of estima-tion errors for all parameters, even those based on the densest network, were quite high relative to the variation observed among monitoring sites in Pennsylvania. All monitoring site observations were within 22.8% of the median concentration for H(+), 17.6% for NO3(-), and 23.1% for SO4(2-) and within 33.9% of the median deposition for H(+), 35.3% for NO3(-), and 36.7% for SO4(2-). Maximum percent errors indicate that estimation errors may severely obscure actual surface features in at least some portions of the estimated concentration and deposition grids in Pennsylvania. Deposition and concentration estimates based on higher density networks were generally more ac-curate; however, the improvements afforded by the additional sites were quite modest. Based on the magnitude of estimation errors, kriging pro-duced the most accurate estimates, although no single algorithm consistently yielded the most ac-curate estimates for all parameters. To maintain a high quality of the environment in a closed bay area, the water quality must be monitored at closely located points. Due to limited availability of measurement devices, obtaining all necessary measurements is often difficult. Remote sensing techniques may solve this problem. Remote sensing data were obtained by multi-spectral scanner for three years in the summer from tral scanner for three years in the summer from 1980 to 1982. Applying regression analysis to the remote sensing data and sea truth data, distribution maps can be obtained for water temperature, transparency, chlorophyll a, and suspended sediments. A correction model was developed to provide statistical data correction, using quadratic equations. To correct for MSS distortion of the data, the three components (reflectance, radiant flux from sunlight, and radiant flux scattered from the terrain), are used from the statistical and physical trom suninght, and radiant flux scattered from the terrain), are used from the statistical and physical viewpoints. The results from the physical model conformed to that of the statistical model. Thus, since each method can be used independently to delete the pass radiance, this method is more flexible than the physical modelling method since the correction pagemeters can be estimated by using correction parameters can be estimated by using the observed MSS data. The statistical method cannot offer any physical meaning even though the physical modeling method gives concrete meaning to the parameters and the correction method. The problem that remains to be solved is applying the method to correct the shadow area produced by clouds (Brunone-PTT)

INSTALLATION OF THE WESTBAY MULTI-PORT GROUND-WATER SAMPLING SYSTEM IN WELL 699-43-42K NEAR THE 216-B-3

Battelle Pacific Northwest Labs., Richland, WA. T. J. Gilmore.

Available from the National Technical Information Service, Springfield, VA 22161, as DE90-001006. Price codes: A03 in paper copy, A01 in microfiche. Report No. PNL-6973, September 1989. 28p, 8 fig, 4 ref, append.

Descriptors: \*Groundwater quality, \*Hanford, \*Monitoring wells, \*Path of pollutants, \*Sampling, \*Washington, \*Well construction, Aquifers, Backfilling, Geohydrology, Groundwater pollution,

In 1988 and 1989, Pacific Northwest Laboratory installed a multiport groundwater sampling system in well 699-43-42K drilled near the 216-B-3 Pond on the Hanford Site in southeastern Washington State. The multiport system will be used to evaluate methods for determining the vertical distribu-tion of contaminants and hydraulic heads in groundwater. The installation was in conjunction with a similar multiport installation near the 300 Area of the Hanford Site. Well 699-43-42K is Area of the manord site. Well 693-43-42A is adjacent to two Resource Conservation and Recovery Act (RCRA) groundwater monitoring wells, which will allow for a comparison of sampling intervals and head measurements between the philig intervals and heat measurements of everet the multiport system and the RCRA monitoring wells. Eight sampling ports were installed in the upper unconfined aquifer by backfilling at depths of 161. If, 174.1 ft, 187.1 ft, 201.17 ft, 217.2 ft, 230.2 ft, 243.2 ft, and 255.2 ft below land surface. However, 243.2 ft, and 255.2 ft below land surface. However, because of damage to the casing during installation, only the top four ports could be used for pressure measurements and sampling until repairs are made. The locations of the sampling ports were determined by the geohydrology of the area and the screened intervals of adjacent groundwater monitoring wells. Installation by backfilling around the multiport system was the first method of its kind on the Hanford Site and proved adequate. For future installations, an alternative method was recommended. amu on the stantord Site and proved adequate. For future installations, an alternative method was recommended, whereby the multiport system would be placed inside a cased and screened well using packers to isolate the sampling zones. DETERMINATION OF EFFECTIVE DIFFU-DETERMINATION OF EFFECTIVE DIFFU-SION COEFFICIENTS FOR GASEOUS AND DISSOLVED ORGANIC SUBSTANCES IN SOIL MATERIAL USING A "STOPPED ELUTION" METHOD WITH HPLC AND GC. Bayreuth Univ. (Germany, F.R.). Chair of Ecolog-ical Chemistry and Geochemistry. K. U. Goss, and K. W. Schramm. Journal of Soil Science ISSCAH, Vol. 42, No. 1, p 47-58, March 1991. 2 fig, 5 tab, 31 ref.

Descriptors: \*Diffusion, \*Diffusion coefficient, \*Gas chromatography, \*Path of pollutants, Adsorption, Algorithms, Data acquisition, Experimental data, Experimental design, Ficks Law, High performance liquid chromatography, Laboratory methods, Leaching, Mathematical analysis, Mathematical equations, Saturated soils, Soil analysis,

Non-steady-state diffusion of chemicals in soil can be described by Fick's second law using suitable effective diffusion coefficients. A 'stopped elution' method was developed to experimentally deter-mine these effective diffusion coefficients for gasemine these effective diffusion coefficients for gase-ous and dissolved substances in dry and water saturated soil. For this purpose a high-performance liquid chromatograph (HPLC) apparatus and a gas chromatograph (SS) were used in combination with soil-filled columns. The method is based on the observed spreading of a substance moving through a soil column, a result of several processes, one of which is diffusion. A suitable experimenes, one of which is diffusion. A suitable experimental design permits the separate measurement of that part of the widening caused by diffusion. The measured effective diffusion coefficients were compared with theoretical values calculated using predictive algorithms from the literature. For liquid-phase diffusion, the maximum deviation between the calculated and the measured values was 34%. The experimental results for gaseous diffusion showed systematic upward deviation from the calculated coefficients. This might be caused by the diffusion of molecules in the adsorbed state, a phenomenon that had been neglected in the calculations. (Author's abstract)

SIMPLE DESIGN FOR SIMULTANEOUS STEADY-STATE INFILTRATION EXPERI-MENTS WITH RING INFILTROMETERS California Univ., Berkeley. Dept. of Soil Science. Water Resources Bulletin WARBAQ, Vol. 26, No. 6, p 935-938, December 1990. 4 fig, 6 ref.

Descriptors: \*Experimental design, \*Infiltration, \*Infiltrometers, \*Measuring instruments, \*Soil water, Analytical methods, Data collections, water, Analytical methods, Data collections, Design criteria, Experimental data, Model studies, Oklahoma, Rainfall-runoff relationships, Ring infiltrometers, Spatial variability, Steady-state infiltration, Watersheds.

A methodology has been developed to characterize the spatial variability of infiltration across a catchment. The methods used involved the collection of a large new set of steady-state infiltration data, without redundancy, for a small rangeland catchment located northeast of Chickasha, Oklahoma. The new data set will then be used as input to a quasi-physically based model for simulations of rangellatrange events. Simplicity of the infiltration a quasi-physically based model for simulations of rainfall-runoff events. Simplicity of the infiltration experiments, and therefore the equipment, was of the utmost importance. To fulfil these criteria, the cylinder-type or flooding-type infiltrometer was selected. A large-diameter, single ring infiltrometer, capable of providing the best measure of true vertical infiltration was assumed. A total of 247 steady-state infiltration measurements were made across the rangeland catchingth using the new across the rangeland catchment using the new methodology. The procedure for measuring steady-state infiltration rates in remote locations steady-state infiltration rates in remote locations was quite successful. The equipment proved to be of a simple design, inexpensive, and rugged. One person could easily manage several installations and coordinate the staggered experiments. The large diameter of the rings facilitated relatively undisturbed surface measurements that minimized boundary and small-scale effects. The limiting factor for the multiple-ring system was that it required large quantities of water. (Korn-PTT) W91-10813

RAPID PRECONCENTRATION METHOD FOR MULTIELEMENT ANALYSIS OF NATURAL FRESHWATERS.

RESTWALERS. Stockholm Univ. (Sweden). Dept. of Geology. P. Andersson, and J. Ingri. Water Research WATRAG, Vol. 25, No. 5, p 617-620, May 1991. 2 fig. 4 tab, 9 ref.

Descriptors: \*Analytical methods, \*Chemical analysis, \*Detection limits, \*Emission spectrometry, \*Metals, \*Preconcentration, \*Sample preparation, \*Water analysis, Aluminum, Beryllium, Cadmium, Chromium, Cobalt, Copper, Iron, Manganese, Nickel, Scandium, Vanadium, Ytterbium, Yttrium,

An inexpensive and rapid preconcentration method was developed which can be applied directly in the field. It is based on coprecipitation with magnesism hydroxide and was applied for Al, Fe, Mn, Zn, Cu, Ni, V, Cr, Co, Be, Y, Sc, and Yb in freshwaters. The method was tested using inductively coupled plasma-atomic emission spectroscopy (ICP-AES) by adding known amounts of metals to distilled water and natural freshwater. The detection distilled water and natural freshwater. The detection limit for ICP-AES can be enhanced more than two orders of magnitude for Al, Y, Sc, and Yb and approximately one order of magnitude for the other tested elements. (Author's abstract)

Ground-penetrating radar is one of the most promising surface-geophysical methods for use in hydrogeologic and surficial mapping studies. A ground-penetrating-radar system was used to study selected stratified-drift deposits in Connecticut. selected stratified-drift deposits in Connecticut. Ground-penetrating radar is a surface-geophysical method that depends on the emission, transmission, reflection, and reception of an electromagnetic pulse and can produce continuous high-resolution profiles of the subsurface rapidly and efficiently. Traverse locations on land included a well field in the town of Mansfield, a sand and gravel pit and a farm overlying a potential aquifer in the town of Coventry, and Haddam Meadows State Park in the town of Haddam. Traverse locations on water included the Willimantic River in Coventry, and Mansfield Hollow Lake in Mansfield. The penetration depth of the radar signal ranged from about 20 feet in fine-grained glaciolacustrine sediments to about 70 feet in coarse sand and gravel. Some land about 70 feet in coarse sand and gravel. Some land about 5 to 11 feet below land surface. Parallel about 5 to 11 feet below and surface. Faranier reflectors on the records are interpreted as fine-grained sediments. Hummocky or chaotic reflectors are interpreted as cross-bedded or coarse-grained sediments. Other features observed on some of the radar records include the till and ce. Records collected on water had distinct water-bottom multiples (more than distinct water-bottom multiples (more than one reflection) and diffraction patterns from boulders. The interpretation of the radar records, which required little or no processing, was verified by using lithologic logs from test holes located along some of the land traverses and near the water traverses. CHANGES WITH TIME OF THE TRANSPORT RATE OF SEDIMENT MIXTURES

#### Field 7—RESOURCES DATA

## **Group 7B—Data Acquisition**

Aberdeen Univ. (Scotland). Dept. of Engineering. R. I. Hardwick, and B. B. Willetts. Journal of Hydraulic Research JHYRAF, Vol. 29, No. 1, p 117-127, 1991. 9 fig, 2 tab, 11 ref.

Descriptors: \*Bed load, \*Sediment sampler, \*Sediment sampling, \*Sediment transport, \*Sediments, Bed-load discharge, Channel armoring, Flumes, Particle size, Trap efficiency.

A novel sediment trap, designed to enable bed-load activity to be related to elapsed time, has been developed. The trap body provides an envelope for the collection of material which is 8 mm x 50 mm x 384 mm, and has a receptacle to accommodate material inadvertently entering the trap during the preparation of the bed at the bottom of this prismatic collector volume. Its two particularly important features are (1) it is transparent, so the accumulation of trapped material can be seen and iy) important reatures are (1) it is transparent, so the accumulation of trapped material can be seen, and (2) the front of the trap is detachable so that samples can be obtained from identifiable intervals during experimentation. The trap was used in a abort pilot experimentation. The trap was used in a short pilot experiment on the armoring of a mixed grain size bed in a small laboratory flume. Despite the limitations of the experiment, significant infor-mation was obtained about the variation with time of bed load transport rate and of the composition of the bed load in the early stages of armoring. The changes of composition were represented in terms of log hyperbolic size distributions. There was confirmation that the transport rate of grain mixcommunation that the transport rate of grain mix-tures is a function not only of flow and grain parameters, but also of time. It was concluded that, for the purpose of validating numerical models of the armoring process, information about bed load composition has higher value than data on changes in the static bed population, because the latter involve severe sampling problems. Thus the trap provides new opportunities in the development of kmowledge about bed winnowing and armoring.

Descriptors: \*Particle size, \*Radar, \*Rain, \*Remote sensing, \*Simulation analysis, Distribution analysis, Rainfall, Reflectivity, Statistical anal-

The error structure of multiparameter radar and surface disdrometer measurements of rainfall has been studied in detail. The radar observable stud-ied were reflectivity, differential reflectivity and X-band specific attenuation. These radar observable were simulated from fundamental considerations which incorporated statistical fluctuations ations which incorporated statistical fluctuations due to the Doppler spectrum and the cross-correlation between H and V-polarized signals at zero time lag. Additionally, natural variations in the raindrop size distribution were incorporated into the simulations by assuming a gamma form for the size distribution. Thus, the radar simulations contain the effects of both statistical fluctuations and physical variations. The simulation results produce realistic scatter as observed with data acquired by the NCAR CP-2 radar. (Author's abstract)

Descriptors: \*Cooperative Water Resources Program, \*Data acquisition, \*Data interpretation, \*Water resources institutes, Economic aspects, Financial aspects, Groundwater quality, Information Water resources data

The Federal-State Cooperative Program is a major U.S. Geological Survey (USGS) activity for the collection, analysis, and reporting of information on the quantity and quality of the Nation's water resources. The fundamental characteristic of the program is that most of the work is undertaken by the USGS through partnership agreements (50:50 matching of funds) with State, regional, and local agencies. The program's main objectives are to: (1) agencies. Ine program's main objectives are to: (1) collect, on a systematic basis, data needed for the continuing determination and evaluation of the quantity, quality, and use of the Nation's water resources, and (2) analyze the data for the purpose of appraising the availability and the physical, chemical, and biological characteristics of surface and groundwater. During fiscal year 1989, hydrolegic data collection, interestrict investigation. logic data collection, interpretive investigations, and research under the provisions of the Cooperative Program were conducted by Geological Survey personnel in offices in every State, Puerto Rico, and several territories in concert with more than 1,000 cooperating agencies. In fiscal year 1989, Federal funding of almost \$59 million was matched by cooperating agencies, who also provided approximately \$8 million unmatched for a total program of about \$126 million. This amounted to more than 40% of the total funds for the Geological Survey's water resources activities. This report presents examples of current (1989) investigations, as well as updated information on the National Water Use Information Program, hydrologic investigations and research related to agriculture, and projects selected and funded under the merit proposal system. METHODOLOGY TO DERIVE WATER-QUALITY TRENDS FOR USE BY THE NATIONAL WATER SUMMARY PROGRAM OF THE U.S. GEOLOGICAL SURVEY.

Geological Survey, Reston, VA. Water Resources

K. J. Lanfear, and R. B. Alexander. Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Open File Report 90-359, 1990. 10p, 2 fig, 2

Descriptors: \*Data acquisition, \*Data collections, \*Data interpretation, \*Data storage and retrieval, \*Water quality, Automation, Statistical analysis, Statistical methods.

Methods were developed to examine a water quality record and, based on the application of a detailed set of trend testing criteria, determine whether a monthly, bimonthly, or quarterly test for monotonic trend could be performed. The trend testing criteria were automated and allowed for an efficient and accurate analysis for trend in an extremely large number of water quality records.
Water quality records for about 3,000 stations and into the discount of the state of t were evaluated as to their suitability for trend testing. From this set of records, it was determined that about 1,100 stations had at least one water quality constituent that met the criteria for trend testing. For those water quality records, a nonpar-

ametric test for monotonic trend, known as the seasonal Kendall test, was applied to three time periods (1970-89, 1975-89, and 1980-89). (Author's W91-11110

AUTOMATIC TRACER-DILUTION METHOD USED FOR STAGE-DISCHARGE RATINGS AND STREAMFLOW HYDROGRAPHS ON SMALL IOWA STREAMS.

Geological Survey, Iowa City, IA. Water Resources Div. P. J. Soenksen.

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 89-4187, 1990. 45p, 26 fig, 1 tab, 14 ref, append.

\*Automation. \*Data acquisition. Descriptors: Descriptors: "Automation, "Data acquisition," Gages, 'Hydrographs, \*Instrumentation, 'Measuring instruments, 'Stage-discharge relations, 'Stream gaging, 'Streamflow, \*Tracers, Evaluation, Flow velocity, Iowa, Rhodamine-WT, Stream discharge.

An automatic system was designed to concurrently measure stage and discharge for the purpose of developing stage-discharge ratings and high flow hydrographs on small streams. Stage, or gage height, is recorded by an analog-to-digital recorder and discharge is determined by the constant-rate tracer-dilution method. The system measures flow above a base stage set by the user. To test the effectiveness of the system and its components, eight systems, with a variety of equipment, were installed at crest-stage gaging stations across lowa. A fluorescent dye, rhodamine-WT, was used as the tracer. Tracer-dilution discharge measurements were made during 14 flow periods at six stations from 1986 through 1988 water years. Ratings were developed at three stations with the aid of these measurements. The most serious problem seems to have been the unequal splitting of flow from a single-head pump for multiple-point injection of single-head pump for multiple-point injection of the dye. A redesign of the splitter, or some other part of the injection line, is needed. Samplers need to be checked and serviced routinely, whether they have been activated or not. Many samples were never collected because of sampler malfunc-tion. An in-line filter system would have reduced tion. An in-line filter system would have reduced or eliminated dye losses to sediment. The possible locations of a pressurized filter in the Manning sampler were limited, and the problem has not been solved. Until some type of filter is developed, it is important to service the automatic tracer dilution stations promptly after a flood, decant only clear water and engine the semple; in a reasonaclear water, and analyze the samples in a reasona-ble amount of time. After a flow, it is important to always service the sampler before servicing the dye injection site. (Lantz-PTT) W91-11111

CLASSIFICATION OF SNOW COVER AND PRECIPITATION USING THE SPECIAL SENSOR MICROWAVE IMAGER.

National Oceanic and Atmospheric Administration, Washington, DC. Environmental Data and Information Service.

N. C. Grody

N. C. Orody. Journal of Geophysical Research (D) Atmospheres JGRDE3, Vol. 96, No. 4, p 7423-7435, April 20, 1991. 14 fig, 2 tab, fig, 22 ref.

Descriptors: \*Classification, \*Microwaves, \*Remote sensing, \*Satellite technology, Algorithms, Atmospheric water, Data acquisition, Mathematical equations, Measuring instruments, Precipitation, Radio waves, Snow cover, Special sensor microwave imager.

Since 1972, various microwave radiometers have been flown aboard polar-orbiting satellites to meas-ure the radiation emitted from the Earth at select-ed frequencies between 6 and 85 GHz. The radidef frequencies between 6 and 85 GHz. The radiation measurements provide unique signatures for identifying surface features and obtaining the temperature and composition of the Earth's atmosphere. The special sensor microwave mager (SSMI) is a seven-channel microwave radiometer that has dual polarized channels at 19, 37, and 85 GHz and a vertically polarized channel at 22 GHz. A detailed evaluation was conducted of all SSMI channels to arrive at the optimum channel selection for global identification of precipitation and snow cover without the use of any ancillary information. The resulting algorithm takes the form of a decision tree that uses the dual polarized channels at 19 GHz and the vertically polarized channels at 22 Hz and 85 GHz. These four channels enable the identification of precipitation from all other atmosidentification of precipitation from all other atmos-pheric and surface features, including snow cover. USE OF A SINGLE-BOWL CONTINUOUS-FLOW CENTRIFUGE FOR DEWATERING SUSPENDED SEDIMENTS: EFFECT ON SEDI-MENT PHYSICAL AND CHEMICAL CHARAC-

TERISTICS.
Geological Survey, San Diego, CA.
T. F. Rees, J. A. Leenheer, and J. F. Ranville.
Hydrological Processes HYPRE3, Vol. 5, No. 2, p
201-214, April/June 1991. 6 fig, 5 tab, 27 ref.

Descriptors: \*Centrifugation, \*Dewatering, \*Laboratory methods, \*Separation techniques, \*Suspended sediments, Particle size, Physicochemical properties, Statistical analysis.

A fundamental problem associated with contaminant transport studies is the collection of enough material to achieve detection of trace contaminants. A study was undertaken to evaluate the use of a single-bowl continuous flow centrifuge (CFC) for dewatering suspended sediment from large volumes (>100 L) of river water. The Sharples Model AS-12 CFC was used as part of a major study of sediment-associated transport of contaminants in the lower Mississippi River system. Sediment-recovery efficiencies ranged between 86 and nants in the lower Mississippi River system. Sedi-ment-recovery efficiencies ranged between 86 and 91% and were comparable to that of other types of CFC units. The recovery was limited by the parti-cle-size distribution of the feed water and by the limiting particle diameter (i.e., 370 nm) that was retained in the centrifuge bowl. There appeared to be no particle-size fractionation within the centribe no particle-size fractionation within the centri-fuge bowl as the median particle size was the same at the top as at the bottom. Particle electrophoretic mobilities were typical of clays coated with organ-ic matter, the charge of which was partially neu-tralized by divalent cations and iron. Contamina-tion by trace metals and organics was minimized by coating all surfaces that came in contact with the samples with either FEP or PFA Teflon and using a removable FEP Teflon liner in the centri-fuge bowl. CFC is a potentially useful tool in investigations of contaminant transport associated

with suspended sediments. It is a rapid technique to dewater sediments collected from large volumes of surface waters. However, because of the apparof surface waters. However, occase of ine appar-ent concentration dependence on collection effi-ciency, and the calculated limiting particle diame-ter, the potential for losing substantial quantities of important suspended mass must be recognized. USE OF 137CS AS A TRACER IN AN EROSION STUDY IN SOUTH LIMBURG (THE NETHERLANDS) AND THE INFLUENCE OF CHERNO-BYL FALLOUT.

Utrecht Rijksuniversiteit (Netherlands). Inst. of Geographical Research.

A. P. J. De Roo.

Hydrological Processes HYPRE3, Vol. 5, No. 2, p 215-227, April/June 1991. 6 fig, 6 tab, 43 ref.

Descriptors: \*Fallout, \*Geostatistics, \*Isotopic tracers, \*Soil erosion, \*The Netherlands, Cesium radioisotopes, Chernobyl, Isotope studies, Mapping, Model studies.

A study has been undertaken to investigate the extent to which the 137Cs content of soils can be used as a tracer to estimate soil erosion rates over the past 30 years in the Etzenrade drainage basin in the past 30 years in the Etzenrade drainage oasin in South Limburg. The Netherlands. In addition, it has been proposed that the extra fallout input of 137Cs from the Chernobyl nuclear accident in 1986 may provide new possibilities for mapping short-term soil erosion rates. Soil samples from 143 sites within the Etzenrade catchment were analyzed to map the 137Cs redistribution using geostatistical intercelation, each of the results of the results of the sentitle of the senti lyzed to map the 137Cs redistribution using geostatistical interpolation methods. The results of the study revealed that Cesium-137 activities on waning slopes were higher than activities on steep slopes. The average net erosion in the Etzenrade catchment for the last 30 years, as calculated from 137Cs data, was estimated to be 418 tons/ha. A comparison of the soil erosion estimates from the 137Cs-based data and the Universal Soil Loss Equation (USLE) erosion model revealed a negative correlation. This implies the need for more advanced models to predict soil erosion patterns. The recent Chernobyl nuclear accident also contributed to the 137Cs activity. Cesium-134 is an exclusive product of Chernobyl and has a 137Cs:134Cs ratio of 1.765:1. However, the Chernobyl input of 137Cs cannot be used as a tracer of soil erosion because of the large spatial variation of 134Cs between the reference sites. Due to the rapid decay of 134Cs, it will not be possible to rapid decay of 134Cs, it will not be possible to separate the sources of 137Cs in the near future in areas significantly influenced by Chernobyl fallout. Therefore, 137Cs can no longer be used as a soil erosion tracer in these areas. (Korn-PTT) W91-11351

# **Group 78—Data Acquisition**

parameters are being monitored in response to the concern of park managers that water levels in this area of the cave are progressively declining. Description of equipment and the methodology used to collect data in this remote area of the cave are presented. Preliminary results for the first 6 months of the study indicate that the lightweight, durable data-logging equipment works successfully in the humid cave environment. Water levels at in the numic cave environment. Water levels at Windy City Lake appear to slightly fluctuate in response to barometric pressure changes, and have declined 0.176 m from January 21, 1988, to July 18, 1988. Water temperature in Windy City Lake and temperature of the air in the cave are constant at 13.8 and 15.0 C, respectively. (Author's abstract)

Any realistic study of the Earth's climate must consider thermal interaction between the atmosphere and the land surface. During the past few years, several highly sophisticated models have been developed to describe exchanges of radiation, heat, and momentum between the land surface and the atmosphere at mesoscales and global scales. Observations on different spectral bands by instruments on board satellites can provide spatially representative values for some of the fluxes and radiative characteristics of the surface, from which the ative characteristics of the surface, from which the parameters needed for heat balance modeling have to be derived. Development of these data sets presents considerable difficulty because the relations between radiative and physical characteristics are generally nonlinear and nonunique; the radiative characteristic anny spectral band is generally determined by several physical characteristics. Relationships between different spectral observations can be used to develop hypotheses concerning the relative importance of different land surface parameters determining these observations, which would have to be confirmed by field observations. Satellite observations for visible, near-infrared, and microwave bands to estimate fluxes at frared, and microwave bands to estimate fluxes at the surface (radiative, soil, sensible, and latent heat) and surface characteristics (albedo, surface temperature, vegetation which can have a signifi-cant impact on cloud cover, rainfall, temperature, and motion fields of the atmosphere, and soil mois-ture) are presented. Interannual variations of some of these satellite observations are analyzed in terms of land surface change. (Medina-PTT) W91-11428

LEVELS AT STREAMFLOW GAGING STA-

Available from Books and Open Files Reports Section, USGS Box 25425, Denver, CO 80225. Techniques of Water-Resources Investigations of the United States Geological Survey, Chapter A19, 1990. 33p, 19 fig, 6 ref, append.

Descriptors: \*Calibrations, \*Data acquisition, \*Gaging stations, \*Handbooks, \*Stream gaging, \*Streamflow, Gages.

The various gages at a newly established gaging station are set to register the elevation of a water surface above a selected level reference surface called the gage datum. The position of this datum is intended to remain unchanged throughout the life of the station. Leveling, a procedure by which surveying instruments are used to determine the differences in elevation between points, is used to set the gages and to check them from time to time for vertical movement. Leveling, done at intervals, usually between 1 and 4 years, determines the elevations of certain points located on or near the different gages by measuring the vertical distances between those points. When the levels are run (that is, the process of leveling is carried out), the gages are checked and reset where necessary. This manual was prepared to provide, in one document, pertinent information on all aspects of leveling related to gaging station operation. It is intended for use in formal and informal training programs in which hydrographers can learn the approved techniques and develop the degree of skill needed to apply them. Procedures, instruments, and equipsurveying instruments are used to determine the which industry and develop the degree of skill needed to apply them. Procedures, instruments, and equipment, including the following, are covered: levelment, including the following, are covered: level-ing concepts and terms; equipment selection, main-tenance, and operation; checking of various types of gages; recording of field notes; adjustment of measured elevations by logical distribution of the measuring errors; and summarizing of results of leveling so they can be readily incorporated in discharge-record computations. The leveling techdischarge-record computations. The leveling techniques described agree with those outlined in surveying textbooks, with instructions prepared by the US Geological Survey (USGS) National Mapping Division, and with instructions for gagingstation leveling developed by the USGS Water resources Division. UNCERTAINTY ANALYSIS FOR A LINEAR PROGRAMMING MODEL FOR ACID RAIN ABATEMENT.

Meteorologischer Dienst der DDR, Potsdam.

Atmospheric Environment ATENBP, Vol. 25A, No. 2, p 231-240, 1991. 5 fig, 2 tab, 25 ref.

Descriptors: \*Acid rain, \*Computer models, \*Model studies, \*Water pollution sources, Acid rain effects, Air pollution, Mathematical models, Simulation, Transfer coefficients.

The influence of uncertain transfer coefficients, describing source-receptor relationships, on the un-certainty of cost-optimal emission reductions, com-puted by the RAINS (Regional Acidification In-formation and Simulation) model, was investigated. Several assumptions on the covariance between the transfer coefficients were tested. One of them was derived from simple assumptions on the under-lying air pollution transport model, thus being more realistic than purely theoretical assumptions. The assumptions of colinearity or statistical independence were not extreme bounds. The dependpendence were not extreme bounds. The dependence of the uncertainty estimates on the prescribed deposition target was also investigated. The optimum emissions of single countries were rather certain for very weak and very stringent deposition targets, having a maximum uncertainty for reading terms of the countries were the control of the countries of the countr tion targets, naving a maximum uncertainty for medium targets. As a quantitative result, the mean value of the five greatest uncertainties of the opti-mum emission of the single countries was less than or roughly equal to the assumed uncertainty of the transfer coefficients. Although sediment pollution is one of the signifi-cant factors in evaluating the mechanisms of water cant factors in evaluating time mechanisms of water pollution, pollutant movements in the sediment make understanding this mechanism difficult. Sedi-ment pollution has been investigated and analyzed by individual municipal organizations, but no com-prehensive study has analyzed sediment pollution. on a national scale in Japan. Sets of data (20,306) measuring 69 parameters, such as oxidation-reduction potential and trace metal levels, were collected from all 47 prefectures for a period of twelve years, from 1972 to 1983. The results were modelled and graphed for each prefecture and sea area, as a comprehensive and direct approach to understanding the pollution. This computation appears to be highly effective in comparing and analyzing the pollution on a comprehensive scale. (Brunone-PTT)

PCG2 is a numerical code to be used with the US Geological Survey modular three-dimensional, finite-difference, groundwater flow model. PCG2 uses the preconditioned conjugate-gradient method to solve the equations produced by the model for hydraulic head. Linear or nonlinear flow conditions may be simulated. PCG2 includes two preconditioning options: modified incomplete Cholesky preconditioning, which is efficient on scalar computers; and, polynomial preconditioning, which requires less computer storage and, with modifications that depend on the computer used, is most efficient on vector computers. Convergence of the solver is determined using both head-change and residual criteria. Nonlinear problems are solved using Picard iterations. This documentation provides a description of the preconditioned, conjugate-gradient method and the two preconditioners, detailed instructions for linking PCG2 to the modular model, sample data inputs, a brief description of PCG2, and a FORTRAN listing. Descriptors: \*Aquifer characteristics, \*Computer models, \*Computer programs, \*Leaky aquifers, \*Model studies, \*Pumping tests, Colombia, Drawdown, Flow equations, Leakage, Observation wells, Storage coefficient, Transmissivity.

A great number of computer programs exist for the calculation of aquifer parameters from pumping test data; however, only a few use the general equation of Hantush and Jacob for leaky aquifers. A method to calculate aquifer transmissivity, storage coefficient, and the leakage coefficient from age coefficient, and the leakage coefficient from pumping test data for a leaky aquifer has been developed. The method is carried out by a computer program and is based on a minimization of the sum of squares of differences between draw-down in the observation well and the theoretical values from the Hantush and Jacob formula. No user defined starting points are necessary. Random error estimates for the parameters have been defined. The method was applied using data from pumping tests performed in leaky aquifers at the Cauca River Valley, Colombia. It was found that the computer method compares well with the conventional methods and that the standard deviation is always lowest with the computer's least-squares approximation. Furthermore, the computer approximation. Furthermore, the computer method has incorporated an error estimation for the parameters. (Fish-PTT)

MODELING LAKE ERIE AS A STOCHASTIC LINEAR RESERVOIR. Cincinnati Univ., OH. Dept. of Civil and Environ-

Cincinnati Univ., OH. Dept. of Civil and Environ-mental Engineering. S. G. Buchberger. IN: International and Transboundary Water Re-sources Issues. American Water Resources Asso-ciation, Bethesda, Maryland, 1990. p 259-268, 4 fig, 2 tab, 12 ref. Ohio Sea Grant Program Project R/ OE-7-PD, NOAA Grant NA88AA-D-SG094.

Descriptors: \*Lake Erie, \*Linear analysis, \*Model studies, \*Stochastic hydrology, Graphical analysis, Hydraulic properties, Reservoirs, Statistical analysis, Water level.

A new approach is presented for forecasting water levels in Lake Erie. In contrast to traditional hy-draulic routing models, the proposed method rep-resents a probability routing scheme. Lake Erie visualized as a stochastic linear reservoir fed by white noise. Starting with mass conservation, ex-pressions are derived for the mean and variance of storage in the stochastic linear reservoir under transient and asymptotic conditions. The reservoir drift function is introduced as a method to evaluate model parameters and as a means to describe the self-regulating behavior of the stochastic linear reservoir. The calibrated model was used to forecast mean September water levels for Lake Erie over a

5-yr period. Annual changes in Lake Erie water 5-yr period. Annual changes in Lake Erie water levels were then computed and plotted against the respective starting lake levels. For example, the mean September water levels in 1987 and 1988 are 5.22 and 3.72 ft, respectively. The corresponding change in elevation is -1.50 ft. This value is plotted against 5.22 ft. Repeating this process for all 130 observations yields 129 points. The change in water level is then regressed against the starting lake level using classic least squares techniques. The resulting regression line, defines the September drift function for Lake Erie. (See also W91-11003) (Lantz-PTT) W91-11029 W91-11029

AMBIENT AIR CO-MODELING IN ALASKA. Alaska Univ., Fairbanks. School of Engineering. R. A. Johnson, M. Anderson, and E. Lilly. IN: Environmental Problems and Solutions: Greenhouse Effect, Acid Rain, Pollution. Hemisphere Publishing Corporation, New York. 1990. p 61-78. 12 fig, 2 tab, 30 ref.

Descriptors: \*Air pollution, \*Air quality, \*Alaska, \*Carbon monoxide, \*Clean Air Act, \*Environmental monitoring, \*Mathematical models, \*Model studies, \*Path of pollutants, Air temperature, Computer models, Environmental Protection Agency, Meteorological data, Meteorological data collection, Model testing, Prediction.

According to the Clean Air Act of 1970, maximum allowable ambient carbon monoxide levels are 9 ppm for eight hours and 35 ppm for one hour. The frequent violation of these standards in Fairbanks and, until very recently, in Anchorage, Alaska, has prompted the US Environmental Protection Agency to encourage strategies intended to reduce Agency to encourage strategies intended to reduce carbon monoxide concentrations. To help gauge the relative merits of various strategies, computer models are commonly used to predict both carbon monoxide emissions and the resultant movement of carbon monoxide through the atmosphere. This study has focused on an assessment of MOBILE3 as a mobile source emissions model and CALINEA as a line course diseasement. as a line source dispersion model in Alaska. We have modified MOBILE3 to allow for the prediction of emissions at ambient temperatures below 0 F and have incorporated available meteorological data for Fairbanks to evaluate CALINE4. The use ese models does allow the approximation trends over time in carbon monoxide levels in trends over time in carbon monoxide levels in Fairbanks, but a lack of more detailed data precludes quantitative prodiction peaks and detailed spatial trends. However, the results to date indicate that these models have the potential to predict carbon monoxide levels in Alaska. (See also W91-11066) (Author's abstract) W91-11070

A simple process-oriented model, called the Alpine Lake Forecaster (ALF), was constructed using data collected from the Integrated Watershed Study of Emerald Lake, Sequoia National Park, California. ALF is able to capture the basic solute patterns during snowmelt in this alpine catchment where groundwater is a minor contributor to streamflow. It includes an empirical representation of regiment uniperal weathering as the only alkalinia. of primary mineral weathering as the only alkalini-ty generating mechanism. During a heavy snow

year, such as the one used for calibrating the model, the model accurately simulated the surface water chemical change in response to the initial ionic pulse from the snowpack and to the dilution that occurs at peak snowmelt. During a light snow year, there is evidence that cation exchange may be a substantial source of alkalinity during the initial phases of snowmelt. Because the model does not consider cation exchange, it over-predicts the acidification during the initial period of snowmelt, and therefore is a conservative predictor. Howevand therefore is a conservative predictor. However, the minimum alkalinity observed in the main inflows to Emerald Lake and in the lake outflow is inflows to Emeraid Lake and in the lake outlinow is accurately simulated by the model. The representation of the lake as simply a mixing volume with no additional chemical reactions is supported by the observations. The model predicts a change of 2 to 5 microequiv/L in the minimum alkalinity of the lake outflow during snowmelt if the deposition of both nitrate and sulfate were doubled and a moderate acidic pulse is released from the snowpack. This change would not be sufficient to acidify the lake. Atmospheric deposition would have to in-crease between two and 18 times the current loadcrease between two and 18 times the current load-ings of both nitrate and sulfate to exhaust the alkalinity of the lake; the precise increase depends on hydrologic conditions and on the pattern of solute release from the snowpack. An acidic rain-storm that exhausted the alkalinity of the lake was observed during summer 1984 after the lake had stratified, and is the likely cause of the acidification of Emerald Lake. SOIL SURVEY INFORMATION SYSTEM: A USER FRIENDLY SOIL INFORMATION

J. L. Anderson, and P. C. Robert. J. L. Anderson, and F. C. Robert. In: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Man-agement. Freshwater Foundation, Navarre, Minne-sota. 1989. p 155-162, 5 fig. 7 ref.

Descriptors: \*Computer programs, \*Data interpretation, \*Data storage and retrieval, \*Information systems, \*Nonpoint pollution sources, \*Soil survey Information System, \*Soil surveys, Computers, Databases, Digital map data, Drainage, Land management, Land use, Maps, Soil management, Soil properties, Vegetation.

Modern soil surveys include soil maps, soil descrip-tions, soil properties, and various soil interpreta-tions prepared for specific uses. One common way to display soil survey information is to create a to display soil survey information is to create a series of simple interpretive maps. This can be done very easily on a microcomputer using the menu-driven Soil Survey Information System (SSIS). The SSIS can access, sort, display, highlight, and print any soil survey data for one section at a time or a similar gridded area. SSIS can also display and overlay other digitized maps such as land use, ownership, vegetation cover types, roads, and drainage. SSIS requires detailed county soil survey reports. The soil survey base map sheets are digitized using a high resolution scanner. Input of soil descriptions, soil properties, and soil interpre-tations is also executed with an interactive program. Maps and summary tapes are displayed on monitors and printed using a standard dot matrix

printer. There continues to be a growing interest in the use of the SSIS for land appraisal, farm management, soil sample location selection, conservation planning, government and local programs, and education. In the future, additional application software will be developed for soil and crop management and soil and the solution of agement, soil and timber management, and soil and road management. Descriptors: \*Computer programs, \*Computerized maps, \*Costs, \*Geographic information systems, \*Landsat images, \*Mapping, \*Nonpoint pollution sources, Data quality control, Data requirements, Digital map data, Maps, Training.

Mapping systems are useful for analyses of data and for communication where geographic location is an important dimension of the information con-tent. It is especially useful for communicating ideas tent. It is especially useful for communicating ideas and concepts because words or text can be supplemented with the visual picture as shown by the map. A map can be computer generated to display information based upon some theme, such as groundwater quality, using a fixed boundary (e.g., county, state, etc.). ATLAS\*GRAPHICS is a thematic mapping system that is relatively inexpensive and it may be a supplementation. matic mapping system that is reliatively inexpensive and is easy to use. It is useful in cases where tasks do not require a true Geographic Information System (GIS) or where budgets are limited. Capabilities of the ATLAS\*GRAPHICS software package include data presentation, construction of overlays, and digitizing new region boundaries. However, several aspects of a mapping system though the second Microscopic according to the control of the several Microscopic and the second However, several aspects of a mapping system should be noted. Mapping systems require a great deal of good quality data. If the quality of the data is inadequate, then the output will suffer. Data also must be tailored to the region being analyzed. If new regions are digitized, data must be available for that region. In addition, the new user must be willing to spend time necessary to learn and operate the system. However, the use of a mapping system will improve retention of the concepts, ideas and information presented, and it will help analyze data for its geographical importance. NATIONAL PESTICIDE USAGE DATA BASE. L. P. Gianessi.

I.F. Connessu.

IN: Agrichemicals and Groundwater Protection:
Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 167-173, 3 tab, 8 ref.

Descriptors: \*Agricultural chemicals, \*Data collections, \*Data storage and retrieval, \*Databases, \*Nonpoint pollution sources, \*Pesticides, \*Water quality, Estimating, Groundwater pollution, Maps, Policy making, Public policy, Regional analysis.

It is often assumed by newly formed public policy-making agencies that there is an up-to-date data-base on pesticide usage available for each county, state, region, or watershed. Unfortunately this not the case. In response to this need, a National Pesticide Usage Data Base has been developed which contains estimates of the average annual usage of twenty-five specific active ingredients in pesticides by crop at the county level of detail. Generally, these estimates are calculated using two coefficients: the percent of acres that are treated coefficients: the percent of acres that are treated and the average annual application rate per treated and the average annual application rate per treated acre. Several operations are performed with these average state coefficients. They are used to calculate county-level estimates assuming that the state average usage coefficients apply uniformly to the counties in the state. Maps are then prepared that show the county usage pattern for the nation. The

#### Field 7—RESOURCES DATA

#### Group 7C—Evaluation, Processing and Publication

purpose behind the development of the National Pesticide Usage Data Base was to be able to evaluate the effects of national policies. National policies can be evaluated in terms of their relative impacts on certain regions, crops, and pesticides. The data base was used in an evaluation of the potential impacts of groundwater protection strategies for the nation. It was concluded that about one-third of the nation's counties can be classified with a potential for groundwater contamination as a result of not only having vulnerable soil conditions but also having significant usage of highly soluble pesticides. SOIL TEC: A COMPUTERIZED SOIL-SPECIF-IC FERTILIZER APPLICATION SYSTEM. CENEX/Land O'Lakes, St. Paul, MN 55164-0089.

IN: A grichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 357-361.

Descriptors: \*Automation, \*Computer programs, \*Data processing, \*Fertilizer management, \*Fertilizers, \*Nonpoint pollution sources, Cost analysis, Crop production, Digital map data, Performance evaluation, Soil classification, Soil properties.

Fertilizer is one of the primary inputs a crop producer must consider when planning a crop producer. Eretilizer application or placement is very important because it affects application rate and other resources. Placement of certain fertilizer materials is of utmost concern since fertilizer rate reductions of up to 79% can occur with some forms of application equipment. Computer technology can now be used to vary the blend of fertilizer and the application rate as a field is crossed. This new method of fertilization is called the SOILECTION SYSTEM. The identification of different soils in a field is accomplished by using both the soil survey map and an infrared photograph. A digitized map is then generated that identifies various areas using different colors. Soils are labeled according to texture or heavy, medium, and light soils. After the map is created, soil samples are taken in each area. Fertility results and recommendations are made based on the yield goals set for each area. The computer can then take a specific field and break it down into the soil types. Fertilizer requirements are then put in the program and a recommendation printout is produced of materials needed and cost per acre. After the recommendation prosess the fertilizer can be spread using a custom designed six to eight compartment fertilizer tox with dispensing wheels. The distribution of fertilizer is controlled by a microprocessor thereby allowing the precise amount of fertilizer from each compartment to be dispensed. (See also W91-11162) (Korn-PTT)

AQUATIC HABITAT MEASUREMENT AND VALUATION: IMPUTING SOCIAL BENEFITS TO INSTREAM FLOW LEVELS.

National Ecology Research Center, Fort Collins,

A. J. Douglas, and R. L. Johnson. Journal of Environmental Management JEVMAW, Vol. 32, No. 3, p 267-280, April 1991. 2 fig, 21 ref.

Descriptors: \*Aquatic habitats, \*Economic aspects, \*Fisheries, \*Instream flow, \*Model studies, \*Streamflow, Benefits, Fish populations, Social aspects, Streamflow depletion, Value, Water allocation, Water resource management.

Since significant public benefits depend heavily on the retention of relatively abundant, free-flowing water within the stream channels, conflicts arising from the allocation of riverine resources are resolved at the bargaining table. Economics offer some useful insights in analyzing conflict resolution within the context of water allocation problems. The relation between aquatic habitat estimation techniques, and the socially optimal allocation of non-market resources are examined in detail. The physical habitat simulation system (PHAB-SIM) developed by the U.S. Fish and Wildlife Service provides a quantitative estimate of the available weighted usable aquatic habitat at various streamflow levels for a given streamreach. A PHABSIM prediction can be displayed as a production frontier in which units of habitat are on one axis, and some market output, such as fish production, is on the other axis. A conceptual problem arises from attempts to match a social benefits trade-off curve with PHABSIM outputs when there is no optimal single steady-state streamflow because the various finish species have evolved through highly variable hydrologic conditions. Angling success is not always a monotonically increasing function of streamflow. The PHAB-SIM model can be combined with an aggregate streamflow benefits curve to elect an optimal streamflow benefits curve to receive any optimal streamflow of the non-market benefits provided by wildlife habitat even more broadly and may lead to a deeper appreciation of the social value of naturally reproducing wildlife populations. KNOWLEDGE-BASED SYSTEMS AND OPERATIONAL HYDROLOGY.

Manitoba Univ., Winnipeg. Dept. of Civil Engineering. S. P. Simonovic.

Canadian Journal of Civil Engineering CJCEB8, Vol. 18, No. 1, p 1-11, February 1991. 3 fig, 38 ref, append.

Descriptors: \*Artificial intelligence, \*Canada, \*Expert systems, \*Network design, \*Operational hydrology, \*Stream gaging, Computers, Hydrology, Open-channel flow, Project planning.

Knowledge-based systems have been known to hydrologists for almost a decade. The application of knowledge-based systems technology in hydrology is natural and appropriate because it contains numerous procedures developed from theory, practice, and experience. Knowledge-based systems of artificial intelligence are reviewed as they apply to hydrology, including an expert system designed to select a suitable method for flow measurement in open channels. An expert system is a computer model consisting of the following components: user interface, explanation subsystem, knowledge base, knowledge acquisition subsystem, knowledge base,

and inference engine. Problems in the field of hydrology can be categorized by: (1) inherent imprecision; (2) paucity and incompleteness of data; (3) fuzzy decision processes, and (4) heavy reliance on expert views (which are themselves vague and imprecise). Experts can function in various capacities in hydrology, including data collection and analysis, storing theoretical knowledge, and storing expertise gained from operational experience. Several expert systems already exist, including HYDRO, HSPF, FLOOD ADVISOR, EXSRM, and SWMM, which cover a wide range of hydrologic problem-solving needs. A decision support system was developed for Environment Canada as a way of selecting the method of flow measurement for open channels. The system will be help Environment Canada in three ways: (1) provided physical conditions at a measurement site, it recommends a list of gaging methods that match service needs and policies; (2) based on the recommended its and additional information about available equipment and structures at the measurement site, the system proposes the most appropriate method; and (3) for the recommended method, detailed instructions are provided to help the user to prepare to take measurements. The system also can be used in planning. (Rochester-PTT)

SATELLITE-DERIVED REFLECTANCE OF SNOW-COVERED SURFACES IN NORTHERN MINNESOTA

National Aeronautics and Space Administration, Greenbelt, MD. Goddard Space Flight Center. D. K. Hall, W. M. Kovalick, and A. T. C. Chang. Remote Sensing of the Environment RSEEA7, Vol. 33, No. 2, p 87-96, August 1990. 4 fig, 4 tab, 33 ref.

Descriptors: \*Data acquisition, \*Reflectance, \*Reflectance techniques, \*Remote sensing, \*Satellite technology, \*Snow cover, Albedo, Energy, Landsat images, Snow depth, Thermal conductivity.

Its high albedo and low thermal conductivity make snow a key component of the global energy balance. Snow depth and reflectance are crucial inputs to General Circulation Models (GCMs), Satellite data from the Landsat Thematic Mapper (TM) have been used to estimate the reflectance of snow and snow-covered surfaces integrated over part (0.45-0.90 micrometers) of the reflective range of the electromagnetic spectrum. The integrated reflectance, Ri, has been computed for snow-covered agricultural and forested areas, and a frozen lake in northern Minnesota using Landsat TM scenes acquired in November 1984 and January 1985. TM-derived reflectances, corrected for atmospheric effects, are mapped for subscenes within the Minnesota TM scenes and reflectances have been color coded. The average Ri within the November 1984 subscene was 0.429 (+/-0.176) whereas the average Ri within the January 1985 subscene was 0.669 (+/-0.236). Snow reflectance is known to increase with solar and sensor zenith angle. The solar zenith angle was 70 degrees at the scene center of the 17 November 1984 scene, and 75 degrees at the scene center of the 04 January 1985 scene. Both areas were predominately snow covered. Lowest reflectances (near 0%) were found in the non-snow-covered agricultural fields. Reflectances of lake ice in the January scene averaged 0.957 (+/-0.0008). In the future, the Moderate Resolution Imaging Spectrometer (MODIS), apart of the Earth Observing System, will enable calculation of Ri over most of the reflective part of the electromagnetic spectrum. Ri may then be used, along with bidirectional reflectance data, to calculate snow albedo, an important input to GCMs and regional energy balarce models. (Author's abstract)

Remote sensing technology can be used for moni-toring changes in surface water quality parameters to provide a rapid assessment of both spatial and temporal variability in surface water quality. Most of the studies that use Landsat data have been of the studies that use Landau data nave been made using either Multi-spectral Scanner (MSS) or Thematic Mapper (TM) data for measuring changes in surface water radiance and reflectance as it is related to suspended sediments and chlorophylls in surface water. A comparison of six con-current Landsat MSS and TM scenes of Moon Lake was made to determine the relationship of Lake was made to determine the relationship of Landsat digital data with suspended sediments, chlorophyll, and temperature in the surface water of the lake. There were no significant differences in best correlations between MSS or TM data with surface suspended sediments. Thus, the advantage of using MSS is the ability to monitor large areas with significantly less data. TM data can be effi-ciently used to monitor smaller lakes and reser-ration. TM Band Lefelence was the only Landest ciently used to monitor smaller lakes and reservoirs. TM Band I reflectance was the only Landsat data that accounted for at least 50% of the variadata that accounted for at least 50% of the variadata that accounted for at least 50% of the variadata that accounted for the same than bility in the chlorophyll data. This would not be adequate for a monitoring program for chlorophyll in sediment-dominated, agricultural lakes, such as Moon Lake. TM thermal data were highly correlated with surface water temperature. TM-measmeet with surrace water temperature. IM-meas-ured surface water temperatures could be useful in determining water balance in small agricultural reservoirs. A monitoring program based an Land-sat MSS and TM scanners can provide data on suspended sediments that would allow the location of reservoirs with significant suspended sedin and allow better conservation assessment and planning. GRAPHICAL METHOD FOR DETERMINING THE COEFFICIENT OF CONSOLIDATION CV FROM A FLOW-PUMP PERMEABILITY TEST. Geological Survey, Denver, CO. R. H. Morin, H. W. Olsen, K. R. Nelson, and J. D.

Gill. Geotechnical Testing Journal, p 302-307, December 1989. 6 fig, 17 ref.

Descriptors: \*Coefficient of consolidation, \*Con-Descriptors: "Coefficient of consolidation, "Con-solidation, "Graphical analysis, "Groundwater movement, "Permeability, "Pumping tests, "Pumps, Darcys law, Data interpretation, Ground-water mining, Hydraulic head, Infusion, Mathe-matical studies, Porous media.

A graphical method has been developed for deter-A graphical method has been developed to deter-mining the coefficient of consolidation from the transient phases of a flow pump permeability test. The flow pump can be used to infuse fluid into or withdraw fluid from a laboratory sediment speci-men at a constant volumetric rate in order to obtain data that can be used to calculate permeability using Darcy's law. When the initial transient-response curve (hydraulic head as a function of time) generated by this test is examined analytically in terms of a one-dimensional consolidation ly in terms of a one-dimensional consolidation process, representative type curve solutions to the associated forced flow and pressure decay models are derived. These curves provide the basis for graphically evaluating the permeability, k, the coefficient of consolidation c, and the coefficient of volume change, m. The curve matching technique is easy and rapid, and it can be applied to results of forced flow tests, both infusion and withdrawal, as well as to subsequent pressure decay records. Values of k, c, and m, for a laterally confined

kaolinite specimen were determined by this graphikaolinite specimen were determined by this graphical method and appear to be in reasonably good agreement with numerically derived estimates (within 20%). Discrepancies between the two sets of results seem to be largely a function of data quality rather than of method of analysis. Where responses of hydraulic head as a function of time are apparently unaffected by experimental sources of error, agreement is excellent (within 4%). Application of this graphical method to triaxial testing has inherent uncertainties, because the solution curves that describe one-dimensional deformation are used to analyze a three-dimensional process. APPLICATION OF UPHOLE DATA FROM PETROLEUM SEISMIC SURVEYS TO GROUNDWATER INVESTIGATIONS, ABU UNITED ARAB EMIRATES).
Geological Survey, Tacoma, WA.
D. Woodward, and C. M. Menges.
Geoexploration GEOXAV, Vol. 27, p 193-212, 1991. 9 fig, 23 ref.

Descriptors: \*Borehole geophysics, \*Data inter-\*Geohydrology, \*Geophysics,

"Geophysics, "Data Interpretation, "Geophysics, "Groundwater resources, "Seismic surveys, "United Arab Emirates, Flow velocity, Groundwater movement, Maps, Oil industry, Surveys, Water table.

Velocity data from uphole surveys were used to map the water table and the contact at the base dune sand/top alluvium in the Emirate of Abu Dhabi. During 1981-83, a reconnaissance seismic survey was conducted for petroleum exploration in Survey was conducted for petroleum exploration in the eastern region of Abu Dhabi. Approximately 2800 km of seismic data, consisting of 92 lines, were acquired in the 2500 sq km concession area were acquired in the 2500 sq km concession area and Ain. Uphole surveys were conducted about 2 km apart along each seismic line, and were used to calculate weathering corrections required to further process in the seismic data. Approximately 1300 uphole surveys were completed in the concession area between March 1981 and June 1983. Reinterpretation of the velocity profiles derived from the uphole surveys provided data for determining the following subsurface layers, listed in descending order: (1) a surficial, unconsolidated weathering layer with a velocity from 300 to 450 m/s; (2) surficial sand, from 750 to 900 m/s; (3) unsaturated, unconsolidated alluvium, from 1000 to un/s; (2) surficial sand, from 750 to 900 m/s; (3) unsaturated, unconsolidated alluvium, from 1000 to 1300 m/s; and (4) saturated, unconsolidated alluvium, from 1900 to 2200 m/s. Two interfaces—the water table and the base dune sand/son alluvium. um, from 1900 to 2000 m/s. Two internaces—the water table and the base dune sand/top alluvium—were identified and mapped from boundaries between these velocity layers. Although the regional water table can fluctuate naturally as much as 3 m/ water table can fluctuate naturally as much as 3 m/y rin this area, an extremely consistent and interpretable water table map was derived from the uphole data throughout the entire concession area. In the northern part of the area, unconfined groundwater moves northward and northewstward toward the Arabian Gulf; and in the central and southern parts of the area, groundwater moves westward away from the Oman Mountains. In the extreme southern area east of Jable Hafti groundwater moves southward into Omale Haffi, groundwater moves southward into Oman. The map of the base dune sand/top alluvium sug-gests a buried paleodrainage network trending westward to southwestward away from the Oman Mountains. These paleodrainages, now buried by dune sand, probably contain alluvial fill and are logical targets for groundwater exploration. (AuW91-11399

Hole 504B in the eastern equatorial Pacific has been the focus of several scientific expeditions during the past few years, where a series of re-entry, drilling, and coring operations has yielded important data regarding the structure of the upper kilometer of the oceanic lithosphere. As part of the extensive downhole experiments program planned for ODP Leg 111 at this site, a borehole televiewer (BHTV) log was obtained across a 355-m vertical section of crustal basement, extending upward from 1531 to 1176 m below the sea floor. The BHTV record was analyzed in terms of both acoustic amplitude and traveltime in order to accurately identify zones of structural failure in the surrounding basement rock. A subsequent examination of breakout frequency vs. azimuth helped identify the orientation of in-situ horizontal principal stresses according to the well substantiated hypothesis that breakouts occur coincident with the direction of minimum principal stress (Sh) where compressive forces are at their greatest. The distribution of breakout frequency vs. azimuth shows the data to be bimodal and orthogonal to a degree that is statistically significant. The Sh directions of the compressive forces are at their greatest. tion is inferred from the primary mode. The or-thogonal pattern indicates that a considerable number of wellbore enlargements were detected coincident with the direction of maximum princi-pal stress (SH). These are interpreted as extension-al fractures produced by localized tensional al fractures produced by localized tensional stresses parallel with the SH orientation. Consideration of various hydraulic fracturing schemes and attendant analyses indicates that these fractures are likely to be induced when the ratio of effective horizontal principal stresses (SH/Sh) is very large in a cylindrical wellborer or is somewhat smaller in a hole exhibiting a slight degree of ellipticity. Inspection of three-dimensional images generated from the BHTV record in the lower portion of the borehole reveals the surprising appearance of pillow lavas at a depth previously assumed to be composed of sheeted dikes. When the ophiolite analogy is applied to contemporary oceanic crust, the transitional unit between the upper pillow lavas and minor flows and the variably metamorphosed and minor hows and the variatist internation prosect diabase dikes below seems to be a complex, gradu-al, and gradational inter-layering of lithologies that extends over a thicker vertical interval than previ-ously thought. POTENTIAL FOR AQUIFER RECHARGE IN ILLINOIS (APPROPRIATE RECHARGE AREAS).

AREAS).
Illinois State Geological Survey Div., Champaign.
D. A. Keefer, and R. C. Berg.
Illinois State Geological Survey, 1990. 1p, 3 fig, 10
ref.

Descriptors: \*Aquifers, \*Artificial recharge, \*Groundwater recharge, \*Illinois, \*Maps, \*Recharge, Bedrock aquifers, Data interpretation, Geohydrology, Groundwater resources, Hydrologic data collections, Infiltration.

The Illinois Groundwater Protection Act has specified that areas of appropriate recharge be identified as part of the State's effort to assess the groundwater resources of Illinois (P.A. 85-863, Section 7.(b)(2)). Appropriate recharge areas, undefined by the Act, have been defined by the Illinois State Geological Survey on a regional basis as the relative potential for recharge to underlying aquifers. This map combines information regarding the distribution, thickness, texture, and hydraulic conductivity of mapped sequences of shallow geologic materials; the distribution of major sand and gravel aquifers; the distribution of major sand and gravel aquifers; the distribution of major bedrock aquifers within 91.2 m (300 ft) of ground surface; and the regional variability of potential for infiltration throughout the state. Combining this geohydrologic information makes it possible to estimate the relative potential for water, available at ground surface as precipitation, to infiltrate the soil surface and percolate down to the uppermost aquifer. The recharge map was produced using a computerized geographic information system to compile, combine, and interpret four statewide map databases: stack-unit map of Illinois; major sand and gravel aquifers; major bedrock aquifers within 300 ft of ground surface; and general soil map of Illinois. This map is a screening tool, designed for regional evaluations of the relative potential for recharge to aquifers. It can also be used to evaluate the vulnerability of aquifers to surficial sources of contamination and to identify regions potentially suitable for sting surficial waste storage or disposal facilities. Constraints of scale and data required the generalization and extrapolation of geologic and soils information. Thus, this map is not accurate enough to be used for site-specific purposes. Selection of specific sites for surficial waste storage or disposal facilities requires detailed geologic mapping and geohydrologic evaluation. (Lantz-PTT)

struction costs, Construction methods, Dallas, Floodwater, Road construction, Structure, Tunnel construction, Tunnels.

Artificial caverns of unprecedented size will solve Dallas Highway's flooding problem. Normally, underground detention chambers would cost too much, but site conditions are right. With low-strength bedrock to cut through and an existing drainage tunnel as the project's starting point, the cavern will save the city over \$4 million. The detention caverns are among many modifications being made to the North Central Expressway (U.S. 75). The road, one of the major north-south free-ways connecting the city's central business district with north Dallas and its northern suburbs, has become overburdened with traffic after many years of development along the corridor. In addition to the caverns, drainage improvements include tunnels under North Central Expressway between Woodall Rodgers Freeway and University Boulevard. Construction of the \$28 million caverns began in April 1990 and is scheduled to be complete in the fall of 1993. The caverns will have a total volume of 71 million gallons. A 40 foot high by 24 foot wide (maximum) vault with curved walls and 16 foot thick pillars was selected as the most workable design based on stress flows around the opening and the maximum and average stresses in the pillar. Patterned, fully resin-encapsulated rock dowels will support the vault at the crown, reinforcing the existing rock above to ensure the formation of a self-supporting rock aroth. Patterned, fully encapsulated rock botts will prevent loosening of the rock in the pillars. Double-position borehole extensometers may measure displacements in the detention vault tunnels. Convergence reference points, in addition to those shown on the fawnings, are also specified for this purpose. (Mertz-PTT)

A three-dimensional (3D) elastoplastic finite-element analysis, which is capable of simulating the dayonace of a tunneling shield and the associated ground losses resulting from the tunneling process, is used to calculate the deformation caused by the excavation of the Thunder Bay sewer tunnel. The soil parameters adopted in the analysis were based on the results determined from stress-dependent triaxial tests. The results of this analysis were then compared with the measured soil displacements. Reasonable agreement was found to exist between the calculated and observed 3D settlement distribution and horizontal displacements at different distances from the tunnel face. This overall agree-

# **ENGINEERING WORKS—Field 8**

Due to the unique nature of hydraulic structures, Due to the unique nature of hydraulic structures, such as breakwaters, it is difficult to use a computer in their design. A study was undertaken in which the computation of the economic optimum rubble-mound breakwater cross-section was executed on a microcomputer. The Rubble Mound Breakwater (RUMBA) computer package was used to compute the optimum rubble-mound breakwater cross-section by minimizing the sum of construction costs and maintenance costs over the lifetime of the structure. In addition, computer aided design (CAD) software was applied in the lifetime of the structure. In audition, computer aided design (CAD) software was applied in the optimization process. Optimization requires a balance between functional effectiveness (benefits) and structural costs, consisting of construction costs and maintenance costs. The quarry production of the cost cosis and maintenance costs. The quarry produc-tion, divided into a number of categories, and long-term distributions of deep water wave heights and water levels, form the basis of the computation. Deep water wave heights are converted to wave heights at site. A set of alternative cross-sections is computed based on both functional performance criteria, and Van der Meer's stability formulae for statistically stable structures. Construction costs statistically stable structures. Construction costs and maintenance costs are determined for each alternative. The optimum is derived by minimizing alternative. The optimum is derived by minimizing the sum of the construction costs and maintenance costs. Moreover, the program provides means to economize the use of the quarry. The computer program proved to be useful in feasibility studies of harbor protection or coastal protection in regions where use can be made of a quarry in the neighborhood of the project site. ROCKING ARMOUR UNITS: NUMBER, LOCA-TION AND IMPACT VELOCITY. Waterloopkundig Lab. te Delft (Netherlands). J. W. van der Meer, and G. Heydra. Coastal Engineering COENDE, Vol. 15, No. 1/2, p 21-39, March 1991. 14 fig, 1 tab, 6 ref.

Descriptors: \*Breakwaters, \*Coastal engineering, \*Concretes, \*Hydraulic structures, Data processing, Mathematical studies, Model studies, Prediction, Stability analysis, Strength, Wave height, Wave velocity

During the late seventies and early eighties several breakwaters were severely damaged along the

coast of the European and African countries in the coast of the European and African countries in the Mediterranean and the Atlantic Ocean. The armour layers of these structures consisted of large concrete units weighing between 20 and 60 tons. These units had a slender shape and were made of unreinforced concrete. A research project was undertaken to investigate the strength of concrete armour units by performing model tests on break-water sections armoured with Cubes and Tetrawater sections armoured with Cubes and retra-pods. Stability tests resulted in a prediction of the number of moved units and the number of impacts as a function of wave height, period and location on the slope. Measurements on acceleration during on the slope. Measurements on acceleration during impacts resulted in a description of the distribution of impact velocities at the center of the unit. These distributions were described by an exponential function with a threshold level and were dependent on the type of unit, the location of the unit on the slope and the wave height. The expressions are applicable in prototype conditions. (Korn-PTT) W91-10786

METHOD OF CALCULATING THE TECHNO-LOGICAL PARAMETERS WHEN DESIGNING HYDRAULIC-FILL DAMS OF SILTY SOILS.

E. L. Vvedenskii. Hydrotechnical Construction HYCOAR, Vol. 24, No. 6, p 354-362, December 1991. 4 fig, 3 tab, 6 ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 6, pp. 5-9, June, 1990.

Descriptors: \*Dam construction. \*Earth dams, Hydraulic fill, \*Soviet Union, Civil engineering, Dam foundations, Design criteria, Hydraulic engineering, Materials engineering, Soils.

There are several advantages associated with constructing a dam by the hydraulic-fill method using local materials. This practice has been used extensively in the Soviet Union in the construction of sively in the Soviet binoin in the constitution of large and medium power and irrigation dams. However, difficulties arise when hydraulic filling of structures is done using fine-grained silty and loess-like soils because of some of their hydrophysical properties. An investigation was conducted of the properties of these soils during settlement and

seepage consolidation, when the physical and n chanical indices of the silty soils may not be suffi-cient for stability of the profile structure. This work demonstrated that, when constructing dams work demonstrated that, when constructing dams of fine-grained silty soils by hydraulic filling, it is expedient to use the technology of layerwise placement of soil with consolidation of each layer. Equations have been developed for calculating the thicknesses of the layers and the period of consolidation of the soil that is needed based on investigations of hydrophysical dynamics of these soils. Equations also have been proposed for predicting the density of hydraulic-filled soil during construction and the distribution of soil in the profile of the the density of hydraulic-filled soil during construc-tion and the distribution of soil in the profile of the structure. A method was developed for calculating technological parameters, particularly the rate of construction of hydraulic-fill structures, calcular-ing the size and number of hydraulic-fill plots associated with one dredge, and predicting seepage discharge into the foundation of dams during their hydraulic filling. CHARACTERISTICS OF MINING OUARRIES ON HYDRAULIC-FILL DUMPS.

V. G. Panteleev, A. V. Bodrova, and G. A.

Hydrotechnical Construction HYCOAR, Vol. 24, No. 6, 9 370-372, December 1991. 1 fig, 3 ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 6, pp. 14-15, June, 1990.

Descriptors: \*Hydraulic fill, \*Land reclamation, \*Mining engineering, Classification, Quarries, Safety, Slope stability.

In the Soviet Union and elsewhere there are sever-al thousand hydraulic-fill dumps, including ash dumps, tailings dumps, slag dumps, and other types, containing billions of cubic meters of pro-duction wastes. It may be duction wastes. It may become necessary to quarry these dumps, either to obtain the wastes for reprocessing or as part of land restoration efforts. A classification and characterization of the quarries that may be developed on these sites was conducted with the aim of calculating the stability of their slopes in order to increase the safety of working on hydraulic-fill dumps. Three types of quarries are recognized: (1) one that is mined from the side, so that the water level of the quarry is always below the hottom: (2) one that is mined from the bottom: that the water level of the quarry is always below its bottom; (2) one that is mined from the bottom; and (3) wastes are excavated from the side of a quarry filled with the water. Types 1 and 2 are applicable to self-compacted dumps, whereas type 3 is most characteristics of hydraulic-fill dumps. s most characteristics of hydraulic-fill dumps. The mining technology employed differs according to the type of dump being mined. Calculation methods have been developed, one for each type of quarry, for determining the appropriate steepness of quarry slopes to provide adequate safety. (Rochester-PTT) W91-11286

diction, Reservoirs, Water management.

As the Soviet Union changes socially in response to 'perestroika,' great emphasis is being placed on improved quality and reliability in large economic facilities such as hydropower plants. Emphasis is shifting from purely engineering concerns to social and ecological concerns as part of the justification for such projects. The planning of many hydropower and water management facilities has become frozen at the feasibility stage as a results of public concern over ecological and sometimes social unreliability of these facilities. Steps that could be taken to improve the planning process include: (1) broad glasnost (openness) and publicity about a proposed facility and planned construction; (2) the wide use of naturalists (ecologists, biologists, climatologists, botanists, ichthyologists, etc.) for solving corresponding problems at the feasibility and design stages; (3) change in the composition and structure of design documents to include a section on "Environmental Protection"; (4) changing from an exclusively economic assessment of projects to one that incorporates assessment of the use of natural resources and payment for their use and pollution; (5) consideration of alternative veruse of natural resources and payment for their use and pollution; (5) consideration of alternative versions of hydropower and water management schemes; and (6) the immediate development of standard reference documents for ecological forecasts, substantiation, and provision of ecological reliability. detention and channel improvement schemes for the Fenay Beck, a main tributary of the Colne River of West Yorkshire, have been designed to alleviate the flooding of domestic and industrial properties to a 50-yr standard of protection. Landscape architects were incorporated into the design teams to cover environmental aspects of the project. A flood-detention dam was constructand project. A food-detenment and was construct-ed mainly of colliery waste. The design of the concrete horseshoe spillway and stilling basin was checked using a 1:40 physical model. The river level would be regulated by an automatic vertical gate activated by downstream water levels. Fol-lowing refusal of the initial plan, a channel-im-provement scheme was adopted. Reduction in valley storage increased downstream flows necessi-tating the enlargement of an old brick and concrete culvert within the ICI works to ensure that there were no detrimental effects within their boundary. An increased benefit/cost ratio of 3.46 as com-pared with 2.55 obtained for the detention scheme was partly due to the application of new standards.

A single oscillator-type hydraulic model of a gate, consisting of a vertical, 20 mm thick, stiff plate with flow underneath, was tested. This gate model had one rotational degree of freedom around a nad one rotational degree of freedom around a horizontal axis, resulting in approximately horizontal movements of the gate edge above a flat bottom. The test program covered gate openings between 5 and 50 mm. With the help of an adjustable leaf spring the natural frequency of the gate model was varied between 5.4 and 86.3 Hz (in air). A force meter was fitted between the leaf spring. A force meter was fitted between the leaf spring. and a stiff frame, to measure the response of the gate model. Numerous inflow vibrations were regate model. Numerous inflow vibrations were re-corded with a rectangular cross-sectioned gate edge. The vibrations appeared to occur in three distinct vibration domains, each characterized by a distinct range of the dimensionless reduced veloci-ty number. Vibrations in another domain, defined by a lower reduced velocity number, were an order of magnitude weaker, and occurred at small-er gate openings. (Author's abstract) W91-10724

OPEN CHANNEL VELOCITY PROFILES OVER A ZONE OF RAPID INFILTRATION. Aberdeen Univ. (Scotland). Dept. of Engineering. A. G. Maclean.

Journal of Hydraulic Research JHYRAF, Vol. 29, No. 1, p 15-27, 1991. 5 fig, 1 tab, 8 ref.

Descriptors: \*Bed load, \*Flow models, \*Hydraulic regineering, \*Infiltration, \*Intakes, \*Open-channel flow, \*Sedimentation, \*Shear stress, \*Surface-groundwater relations, Boundary layers, Boundary processes, Flow velocity, Physical models, Shear

The design of a bed-type river intake requires serious consideration of its effect on the movement of bedload in the suction zone. The accurate esti-mation of the boundary shear stress depends on a mation of the boundary shear stress depends on a knowledge of the flow structure over the suction zone. Laboratory measurements have been made of the modification of the velocity profile in an open channel caused by a region of rapid infiltra-tion through the bed, such as that associated with a bed-type river intake. The results have been ana-lyzed to provide an estimate of bed shear stress in the suction zone. The measurements were obtained using Laser-Doppler anemometry, and were com-pared with hot-wire measurements over a similar pared with hot-wire measurements over a similar zone of suction in a wind tunnel. It was concluded zone of suction in a wind tunnel. It was concluded that the flow structure over a zone of rapid infiltration in an open channel is an inner boundary layer across which the shear stress changes rapidly, above which is a logarithmic region in which the flow structure is effectively unaltered by the presence of suction. The velocity gradient in the logarithmic region decreases as the abstraction velocity increases. The increase in shear stress at the bed caused by suction is best evaluated by considering the ratio of velocities with and without suction at a caused by suction is best evaluated by considering the ratio of velocities with and without suction at a reference height close to the bed. A height of 2 mm was found to match the available data most closely in this case. (Fish-PTT) W91-10984

DRAG ON VERTICAL SILL OF FORCED JUMP.

Nihon Univ., Tokyo. Dept. of Civil Engineering. I. Ohtsu, Y. Yasuda, and Y. Yamanaka. Journal of Hydraulic Research JHYRAF, Vol. 29, No. 1, p 29-47, 1991. 24 fig, 1 tab, 12 ref.

Descriptors: \*Drag, \*Energy dissipation, \*Hydrau-lic engineering, \*Hydraulic jump, \*Spillways, \*Water pressure, Flow characteristics, Flow equa-tions, Hydraulic design, Hydraulic structures, Hy-drostatic pressure, Pressure distribution.

To dissipate the energy of a high-speed discharge flowing down a spillway, it is common to use a hydraulic-jump-type energy dissipator. As a basis for designing a forced hydraulic-jump-type stilling basin, the pressure magnitude on the upstream and downstream faces of a continuous-vertical sill has been investigated experimentally, and the nature of the pressure distribution on the faces of the sill has been examined. The flow conditions of the stream passing over the continuous-vertical sill are classified as Type I jump (the flow condition upstream of the sill is influenced by the downstream depth), Type II jump (the upstream flow is not influenced by the downstream depth), and Spray condition (the supercritical flow impinges directly on the sill and splashes without forming a jump). An experimental formula for the drag force acting on the sill has been proposed considering the characteristics of the flow condition over the sill, which makes it passing over the continuous-vertical sill are classi-

#### ENGINEERING WORKS—Field 8

Descriptors: \*Flow equations, \*Hydraulic engineering, \*Mathematical studies, \*Numerical analysis, \*Open-channel flow, \*Shallow water equations, \*St Venant equation, Channel flow, Model testing, Prediction, Shallow water, Shock waves.

An important aspect of numerical schemes is to be able to check their predictions against suitable test problems, preferably ones for which an exact solution is available. A one-dimensional problem of shock (bore) reflection was examined for the two-dimensional problems of the control of the two-dimensional problems. shock (bore) reflection was examined for the two-dimensional shallow water equations with cylindri-cal symmetry in order to derive an exact similarity solution. The nonlinear shallow water (St Venant) equations govern the flow of water in a channel whose lower surface is flat. The shock-reflection test problem was stated in a single 'radial' coordi-nate and the differential equations for the similarity colotion were derived and solved compericults in solution were derived and solved numerically in conjunction with the Rankine-Hugoniot shock reconjunction with the Rankine-Angoinot sack re-lations. This result is particularly useful for testing the symmetry properties, accuracy, and shock-cap-turing capabilities of a code for the two-dimension-al shallow water equations. (Fish-PTT) W91-10987

Watercourse S 333 at Maarkedal (Belgium) drains a hilly area. The use of concrete pipes as revetment for smaller channels in hilly regions is a hydrauli-

cally justifed choice. Bed erosion of the watercourse is efficiently prevented even if the pipes are installed with less precision or have rather large openings between two adjacent tubes. Water openings between two adjacent tuoes. Water depths were obtained from water level recorders and a measuring weir allowed discharge determinations. Only peak values were considered to determine the roughness coefficients. Water level calculations were used without considering additional energy loss coefficients, so that all the chambel irresulted the service work of the company of cancinations were used without considering additional energy loss coefficients, so that all the channel irregularities were included in the roughness coefficients. Over nearly the whole range of flows, the roughness coefficient value decreased with increasing water depths. A value of 43 m(1/3)/s) was calculated at a depth of half the diameter of the pipe. This type of revetment proved to be an excellent protection against erosion, even in reaches with steep slopes, where the supercritical flow occurs. Flow velocities in water courses having a revetment make of half concrete pipes remain generally high as a result of the slope of the longitudinal section on the one hand and the lower wall roughness of the concrete revetment pipes compared to natural vegetation on the other hand. An important self-cleaning effect is obtained, making these watercourses practically maintenance free. A minimum pipe diameter of 80 cm is recommended to reduce the influence of an excessive bank vegetation especially during summer. (Author's abstract) W91-11431

Tests were conducted on a 1:30-scale model of the Tests were conducted on a 1:30-scale model of the Melvin Price Auxiliary Lock, Alton, Illinois, and on a 1:12-scale model of the rotary valve proposed for use as the filling and emptying valves. The lock model was built to study the effect of the rotary valves on the filling and emptying characteristics, the adequacy of the vertical slide gates to be used as a backup system, and the effects of flow through the adiacent spillway have on the lock discharge as a backup system, and the effects of flow through the adjacent spillway bays on the lock discharge outlets during emptying operations. Unsatisfactory flow conditions were observed during spillway discharges in the vicinity of the lock discharge outlet caused by discontinuity along the lock wall between the spillway pier and the discharge outlet. A wall was installed that streamlined the discontinuity and provided satisfactory flow conditions during spillway releases. Tests with rotary valves, when compared to a similar conventional system using reverse tainter valves, indicated significantly longer emptying times and slightly longer filling times. The rotary valve model was built to study the hydraulic forces acting on the valve and pressure fluctuations on and around the valve, and to observe conditions in the vicinity of the valve during steady-state and dynamic operating condiduring steady-state and dynamic operating condi-tions. The maximum pressure difference across the gate occurred when the valve reached between a 50% and 60% open position during an emptying operation. The maximum torque on the valve oc-curred when the valve reached a 50% open posi-tion. (Lantz-PTT) W91-10723

CONVERTER APPLICATION FOR MINI HYDRO GENERATION.

A. Hutarew

International Water Power and Dam Construction IWPCDM, Vol. 43, No. 5, p 17-19, May 1991. 2

Descriptors: \*Electric converters, \*Electrical equipment, \*Hydroelectric plants, \*Inverters, Control systems, Germany, Hydraulic machinery, Hydraulic machinery, Hydraulic machinery, Hydraulic machinery, Hydraulic machinery ectric power, Performance evaluation,

Since 1983, the idea of adapting inverter units for power generation in water power stations has been considered but not implemented. The development of asynchronous drives for high-speed railroad trains led to the development of this technology and reduced prices considerably. In 1989, a converter unit was ordered for use as a generator at the Rottenburg (Germany) municipal hydroelectric plant, which is in the process of being refurbished. Inverters are static frequency converters with impressed current in a DC link and are included for speed variation of three-phase case with impressed current in a DC inix and are in-tended for speed variation of three-phase cage motors. Speed regulation is carried out by a simple control system based on adjustment by frequency setting and internal voltage control. Theoretical studies suggest that the technology will provide a wide range of efficiencies while dispensing with while range of enticiencies while dispensing with the mechanical system traditionally used to control frequency output. Ultimately, developments in converter technology may allow asynchronous generators in hydro plants to operate effectively at almost any speed. The Rottenburg power station began generating electricity in March 1991; test runs on the pilot plant are under way. (Rochester-PTT) PTT W91-11213

EXPERIENCE WITH LOW-HEAD HYDRO-PLANT FREQUENCY CONTROL. Sulzer Bros. Ltd., Winterthur (Switzerland).

Descriptors: \*Control systems, \*Electrical equipment, \*Frequency control, \*Hydraulic machinery, \*Hydroelectric plants, \*Low-head hydroelectric plants, Mathematical models, Performance evalua-

Generally, low-head hydroelectric units operate in a base load mode, which means that they deliver a base load mode, which means that they deliver power according to actual water flow and do not participate in frequency regulation. The speed governor only acts in the speed/no load condition to synchronize the output to the grid. A speed control system covering the whole load range of an isolated hydro plant has been developed, based on a proportional-integral governor and an electronic feedback module. A mathematical model was used to predeternine settings shortening the time of to predetermine settings, shortening the time of commissioning the system. Plant experiments were conducted and confirmed that, with an additional conducted and confirmed that, with an additional feedback module, the speed/frequency control loop was stable and damped sufficiently well over the whole load range in isolated operation. At partial loads below 50%, the speed control performance was acceptable, even for large load disturbance. Beak feedured designed in the control of turbances. Peak frequency deviations increased markedly, and control was much slower near to full load because of the necessary compensation for the increasing water hammer effect. (Rochester-PTT W91-11214

DEVELOPMENT OF SMALL HYDRO FOR REMOTE AREAS OF NORTHERN PAKISTAN. Northern Areas Public Works Dept., Gilgit (Pakistan).

The Northern Areas of Pakistan, a remote region characterized by difficult terrain, could not be economically connected to the country's national economically connected to the country's national grid. Small hydro schemes therefore have a particularly important role to play in providing much needed supplies of electricity for the local population and stimulating the overall development of the area, particularly with regard to light industries and tourism. At present 48 stations operate to provide electricity for a third of the population. Work on another 30 stations is in progress and more are being planned. The development of small hydro schemes has changed the socioeconomic hydro schemes has changed the socioeconomic pattern of these areas and positive effects on the environment and ecology can be expected soon. Of the two types of turbines already in use (crossflow and Francis), experience has shown that the crossflow runners wear out relatively quickly. Frequent breakdowns are caused by poor metallurgy in the manufacture of guide vanes and runners. This ex-perience has led to a tendency to prefer Francis runners. Recently, growing populations and an increasing demand for electricity have forced planners to choose high-capacity (625 kVA to 123 kVA) Francis or Pelton turbines. (Rochester-PTT) W91-11215

DAMS AND SUSTAINABLE DEVELOPMENT IN BRAZILIAN AMAZONIA.

Monosowski Associate Consultants, Sao Paulo (Brazil).

E. Monosowski.

International Water Power and Dam Construction IWPCDM, Vol. 43, No. 5, p 53-54, May 1991.

Descriptors: \*Amazon River Basin, \*Brazil, \*Environmental effects, \*Environmental impact, \*Hydroelectric plants, \*Hydroelectric power, Dams, Economic aspects, Regional analysis, Regional planning, Social aspects, Water resources management

Hydropower dams are responsible for the production of about 95% of the electricity consumed in tion of about 95% of the electricity consumed in Brazil and they will remain its major source for at least the next 30 yr. Experience gained in recent years in Brazil's Amazonian region has encouraged the adoption of policy for the regional insertion of dams by a national power authority. Lessons learned in the past are therefore contributing to a review of environmental management practice. Be-cause of the topography of the Amazonian region, cause of the topography of the Amazonian region, the filling of reservoirs transforms large rivers into artificial lakes of vast dimensions (e.g., Tucurui reservoir, 2460 sq km, Balbian reservoir 4000 sq km, and planned Babaquara reservoir possibly 7000 sq km). Regional impacts on hydrology, changes in regional economic activity, pollution resulting from new industries, and deforestation were mainly unexpected consequences of existing dams. In the long-term, these impacts may reduce the regional development alternatives and even isonregional development alternatives and even jeop-ardize economic production of electricity in the region. To avoid these unintended consequences in the future, a broadened approach to planning and decision making is recommended. Interests, other than commercial interests, should be considered. The hydro projects should be constructed within the context of a regional growth plan and a sustainable development strategy for Amazonia as a whole. (Rochester-PTT) W91-11216

HYDROELECTRIC TURBINE SEITING: A RATIONAL APPROACH.

Canadian Journal of Civil Engineering CJCEB8, Vol. 18, No. 1, p 27-35, February 1991. 2 fig, 6 tab, 15 ref.

Descriptors: \*Hydraulic machinery, \*Turbines, Design criteria, Hydraulic engineering, Hydroelectric power, Mathematical equations.

There are no standards for the setting of a hydraulic turbine with respect to the tailwater level. Manufacturers rely on hydraulic model data to determine the required protection against cavitation, and they never publish these data. Utilities and consultants must rely on the interpretation of published statistical data relating submergence to vari-ous turbine parameters. An alternative approach has been devised wherein a general equation is developed relating the submergence of a stainless steel or cast steel runner to the number of runner blades, the plant capacity factor, the turbine throat velocity, the tailwater level above sea level, the velocity, the tailwater level above sea level, the water temperature, and the acceptable amount of cavitation. The equations have been tested on 39 different power plants having either horizontal or vertical axis Kaplan, propeller, or Francis turbines, both large and small. The equations are particularly useful for establishing the turbine diameter and setting during feasibility assessment and for comparing the manufacturer's suggested turbine parameters in the final design stage. The countries rameters in the final design stage. The equations also can be used to determine the capacity of a new runner in an existing casing. (Author's abstract) W91-11274

FLOW THROUGH GATED CONDUITS AT PARTIAL AND FULL GATE OPENINGS.

Agriculture Canada, Regina (Saskatchewan). Research Station.

Prairie Farm Rehabilitation Administration (PFRA), a branch of Agriculture Canada, has responsibility for care and custody of approximately 120 dams built for irrigation, stock watering, and other uses. Most of these dams are between 5 and 20 m in height and include riparian or irrigation outlet structures controlled by vertical slide gates. Criteria were developed to evaluate the discharge configuration at the gate. Relationships were determined between discharge, upstream energy level, mined between discharge, upstream energy level, gate opening, and downstream submergence. A test program based on hydraulic modeling was conducted. Two gate shapes were tested: a circular gate similar to the Armco Model 20-10C and a square gate similar to the Armco 55-10. It was shown that a unique contraction coefficient exists for a given gate at a given gate opening, but that discharge for a given unstream energy level dedischarge for a given upstream energy level de-pends on whether the gate discharges freely or is submerged downstream. Situations involving par-tial submergence generally do not need to be accounted for in practice; such situations generally occur only at relatively large gate openings. The study showed that, for the method of analysis used, the contraction coefficients are quite similar for two very dissimilar gates controlling a circular section. While this tends to imply that contraction coefficients for gated sections are fairly insensitive to gate shape, the results of tests on a greater variety of gates would be required to prove this. INTAKE DEVICES FOR DREDGES WITH SUB-MERSIBLE SUCTION PUMPS.

S. P. Ogorodnikov, I. I. Mikheev, A. E. Kulakov, and N. N. Kozhevnikov.

No. 6, p 372-374, December 1991. 2 fig, 3 ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 6, pp. 15-16, June, 1990.

Descriptors: \*Dredging, \*Hydraulic machinery, \*Intakes, Design criteria, Hydraulic engineering, Hydraulic rippers, Nozzles, Optimization, Performance evaluation, Pumps, Soviet Union.

In the Soviet Union and elsewhere, experimental models of dredges with submersible centrifugal suction pumps have been created and tested. High efficiency has been demonstrated: with a given intake of the mud-and-water mixture and hydraulic transport, the output can increase by 1.5 times. A transport, the output can increase by 1.5 times. A study was conducted aimed at optimizing the intake portion of the transport process as it relates to these submersible pumps used in dredging. First, it was shown that submersible pumps are effective not only at large dredging depths (i.e., within the limit values of the vacuum in the suction line), but at the usual depths (less than 10-12 m), when cavitation effects in the suction pump are small. The Kalinin Polytechnic Institute designed an improved intake device for the 330-501 number 463 ne Raimin Poytecnic institute designed an improved intake device for the 350-50 L number 463 dredge with a submersible centrifugal suction pump of type 20R-11. The improved intake device consisted of a modernized suction nozzle and a hydraulic ripper. During tests, the hydraulic trans-port system of this dredge consisted of two 20Rport system of this dredge consisted of two 20R-11M pumps (bilge and submersible) connected in series. The water discharge of each pump was 3600 cu m/hr; the head of the submersible pump was 30 m, whereas it was 60 m for the bilge pump. The optimization of parameters of the intake device on the 350-50L dredge with the submersible pump led to an output increase on sand soils of 51% with the ripper and 26% without the ripper. Later tests with a modified device confirmed these results. (Rochester-PTT) W91-11287

OPERATING EXPERIENCE AND SUGGESTIONS ON RECONSTRUCTION OF THE TURBINES OF THE DNEPR-I HYDROELECTRIC

I. P. Ivanchenko, and V. I. Platov

Hydrotechnical Construction HYCOAR, Vol. 24. No. 6, p 389-397, December 1991. 4 fig. 2 tab, 5 ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 6, pp. 26-31, June, 1990.

Descriptors: \*Dnepr River, \*Hydraulic engineering, \*Hydroelectric plants, \*Soviet Union, \*Turbines, Design criteria, Efficiency, Numerical analysis, Performance evaluation, Rehabilitation, Reli-

A review of the 40-yr operating experience at the Dnepr (Soviet Union) hydroelectric station as it relates to reliability and operating efficiency at the Dnepr-I part of the hydroelectric station has demonstrated a need to rebuild the turbines. The residual of the property of the prope onstrated a need to rebuild the turbines. The reasons are as follows: (1) the present operating conditions differ markedly in head from those in the original design, with the result that turbine efficiency in the main load regimes is 5-8% lower than the optimal; (2) because of numerous welds of the blades during repair of cavitation erosion, deformation of the blade system has occurred, resulting in a loss of turbine efficiency of 1.5%; (3) the existing runners are of obsolete design; and (4) reliability indices of the equipment are decreasing steadily. Computer calculations were conducted with the aim of selecting the optimal parameters (turbine power and speed) of a new turbine at the time the reconstruction of the hydroelectric station takes place. These calculations were done in contime the reconstruction of the hydroelectric station takes place. These calculations were done in conformity with the actual operating conditions. On the basis of the criterion of the maximum weighted average efficiency, the new turbine should have the following characteristics: rotation speed 88.2/min, rated power 74.0 MW at head = 35.5 m, and average efficiency 94.8%. On the basis of the criterion of obtaining a maximum power on the new turbine, the following values would be desirable: rotation speed 90.9/min, rated power 78.0 MW at head = 35.3 m, and average efficiency = 94.5%. To increase the efficiency and operating reliability of the existing equipment (before reconstruction), it is recommended that the power of the turbines be limited by opening the gate apparatus. STABILITY OF HYDROPOWER CONSTRUCTION PROGRAMS,

B. L. Erlikhman. Hydrotechnical Construction HYCOAR, Vol. 24, No. 6, p 418-422, December 1991. 5 ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 6, pp.

Descriptors: \*Electric power production, \*Hydro-electric power, \*Soviet Union, Caucasus, Central Asia, Dam construction, Economic aspects, Man-agement planning, Siberia.

The gross hydropower potential of the Soviet Union can be taken with some certainty to be 4 trillion kWh/yr, but the calculated technically feasible potential of 2.1 trillion kWh/yr may be an underestimate. More than 25 yr ago, the total economic potential was calculated as 1095 billion kWh/yr. Increased demands for water in multipurpose reservoirs, the age of some of the plans for hydropower stations, and the changing role of hydropower in the overall electrical supply industry make the problem of calculating future hydropower growth more complex than in the past. Considerable replanning of hydrostations and schemes lies ahead. Without this effort, the value of the economic potential of hydropower resources The gross hydropower potential of the Soviet schemes has an earl. Without his error, the value of the economic potential of hydropower resources cannot be refined and the drawing up of the program of development of hydropower cannot be completed. Preliminary calculations show that the previously calculated economic potential of hydropower resources of the Caucasus and parts of the Siberian and Central Asian regions will remain the same or increase, whereas in central, southern, and northwestern regions of the European USSR, western Siberia, and certain parts of the Far East the potential will decrease. Descriptors: \*Hydraulic machinery, \*Hydraulic models, \*Pumping plants, \*Pumping stations, \*St Johns Bayou, Channel flow, Costs, Flow pattern, Missouri, Model studies, Pumps.

The design of the proposed St. Johns Pumping Station at New Madrid, MO, consisted of three vertical pumps with a total capacity of 1,000 cu ft/s. A 1:11.5-scale pumping station model of the pump intakes, sump, and inlet channel was used to investigate and develop a practical design that would provide satisfactory hydraulic performance. The model tests revealed that prototype construc-tion costs could be reduced by reducing the sump length and the angle of the approach wing walls. Initially, adverse flow distribution and excessive antiany, adverse now distribution and excessive swirl were measured in the pump intakes. A pump intake design was developed that had insignificant swirl and provided good flow distribution for an-ticipated flow conditions. (Author's abstract) W91-11588

CHANGE IN PORE SIZE DISTRIBUTION OWING TO SECONDARY CONSOLIDATION

New Brunswick Dept. of Transportation, Fredericton. Materials and Research Branch.
F. J. Griffiths, and R. C. Joshi.

adian Geotechnical Journal CGJOAH, Vol. 28, No. 1, p 20-24, February 1991. 4 fig, 2 tab, 24

Descriptors: \*Clays, \*Compressibility, \*Pore size, \*Soil mechanics, \*Soil structure, Consolidation, Deformation, Permeability, Pore pressure, Soil analysis, Soil porosity, Soil properties.

Secondary consolidation has long been utilized as a Secondary consolutation has long ocen unitized as a useful concept for settlement analysis. The rate-setting mechanism is viewed as the permeability of the soil during the primary phase, whereas second-ary compression is considered as the deformation that occurs at a constant effective stress. The exact nature of and reason for secondary compression in clay soils has been evaluated in a series of laboratociay soils has been evaluated in a series of laboratory experiments conducted using mercury-intrusion porosimetry (MIP). The amount of secondary consolidation was varied for several samples of three soil types by holding the consolidation stress steady at 120 kPa for different durations. The steady at 120 kPa for different durations. The results of the investigation revealed that secondary deformation could be seen as a reduction in pore volume generally in the 100-1000 nm range. Examination of the pore size distribution curves revealed that secondary consolidation could not be due solely to the deformation of micropores. Rather, reduction was due to a loss of entrapped pore space as well as a component of volume change in the free pores. The relative degree of change in total, free and entrapped porosity appeared to be related to the proportion of each initially in the sample. The greater the proportion of free pore space, the greater the amount of the reduction in free pore space owing to secondary compression. (Korn-PTT)

FINITE-ELEMENT ANALYSIS OF SOFTEN-ING EFFECTS IN FISSURED, OVERCONSOLI-DATED CLAYS AND MUDSTONES. Alberta Univ., Edmonton. Dept. of Civil Engi-

N. Yoshida, N. R. Morgenstern, and D. H. Chan. Canadian Geotechnical Journal CGJOAH, Vol. 28, No. 1, p 51-61, February 1991. 17 fig, 1 tab, 36

Descriptors: \*Clays, \*Finite element method, \*Model studies, \*Soil mechanics, \*Soil properties, \*Soil strength, Deformation, Excavation, Plasticity, Pore pressure, Slopes, Soil absorption capacity, Soil stabilization, Strength, Stress, Yield equations.

Fissured, overconsolidated clavs and mudstones rissured, overconsolidated clays and mudstones soften with time due to water absorption upon unloading. The effect of softening is a decrease in shear strength accompanied by a diminishing tendency to dilate. The reduction of shear strength due to softening can be represented as a lowering of the failure envelope and a reduction in the high nonlinearity at low stress levels. The softening nonlinearity at low sites levels. The softening process may be formulated in terms of a time-dependent yield surface, and the finite-element method can be extended to analyze softening effects. A finite element analysis was carried out for fects. A finite element analysis was carried out for a cut slope and revealed variations in vertical and horizontal displacements with time. Time-dependent development of deformations and plastic zones were computed as yielding progressed. The displacements developed when the excavation was completed but before the pore-water pressures were replaced with steady-state values taken as zero. This allowed an evaluation of the influence of the pore-water pressure change on the slope behavior. The pore-water pressure replacement rebehavior. The pore-water pressure replacement resulted in large upward displacements at both the crest and the toe. Horizontal displacement initially increased gradually at both the crest and the toe for a period of 50 years after excavation. However, for a period of years after excavation. However, horizontal displacement increased rapidly as the slope approached collapse, in association with the progression of yielding. Vertical displacement at the toe followed the same trend as the horizontal the total own the same trend as the horizontal displacement, but at the crest only a small downward displacement developed. The lifetime of the slope was calculated as 95 years. (Korn-PTT) W91-10776

ELECTROOSMOTIC STRENGTHENING OF SOFT SENSITIVE CLAYS.

University of Western Ontario, London, Dept. of Civil Engineering. K. Y. Lo, I. I. Inculet, and K. S. Ho.

Canadian Geotechnical Journal CGJOAH, Vol. 28, No. 1, p 62-73, February 1991. 14 fig, 4 tab, 25 ref. National Sciences and Engineering Research Council of Canada Grant No. OPG0007745.

Descriptors: \*Clays, \*Electro-osmosis, \*Pore pres-sure, \*Soil mechanics, \*Stress analysis, Analytical techniques, Consolidation, Electrodes, Experimen-tal design, Measuring instruments, Soil moisture retention, Soil properties, Soil strength, Stress-

A comprehensive experimental investigation on the electroosmotic strengthening of soft sensitive clay was performed to assess the effectiveness of the treatment and to study the mechanism of the process. A specially designed electroosmotic cell was developed to prevent gas accumulation near the electrodes, to allow better electrode-soil contact, and to improve the treatment efficiency. This apparatus also enables the monitoring of the generated negative pore-water pressure along the sample length, settlement, voltage distribution, and current variation during treatment. The investigation covered two different types of soil trimmed at different orientations: the vertically and horizontally ent orientations: the vertically and horizontally trimmed overconsolidated Wallaceburg clay and the vertically trimmed slightly overconsolidated soft sensitive Gloucester (Leda) clay. Results of soft sensitive Gloucester (Leda) clay. Results of this study showed that the voltage distribution and induced negative pore pressure at equilibrium along the sample are linear with steady current flow across the sample, indicating that the elec-trode design in the electroosmosis test apparatus is efficient. The electroosmotic consolidation curve is similar to that of the conventional consolidation curve and the preconsolidation pressure was insimilar to that of the conventional consolidation curve, and the preconsolidation pressure was increased by 51-88% with an applied voltage up to 6V. The undrained shear strength increased to a maximum of 172%, and the moisture content decreased by 30%. The technique of electrode reversal was employed, and a relatively uniform strength increase between the electrodes was obed. (Author's abstract) W91-10777

FIELD TEST OF ELECTROOSMOTIC STRENGTHENING OF SOFT SENSITIVE

K. Y. Lo, K. S. Ho, and I. I. Incutet. Canadian Geotechnical Journal CGJOAH, Vol. 28, No. 1, p 74-83, February 1991. 14 fig. 1 tab, 13 ref. National Sciences and Engineering Research Council of Canada Grant Nos. OPG0007745 and

Descriptors: \*Clays, \*Electro-osmosis, \*Field tests, \*Soil mechanics, \*Soil strength, Cathodes, Electrodes, Instrumentation, Interstitial water, Monitoring. Polarity. Soil properties.

A field test was undertaken to assess the effectiveness of electroosmosis in strengthening the soft sensitive (Leda) clay at the Gloucester test fill site. Specially designed copper electrodes were in-Specially designed copper electrodes were installed to prevent gas accumulation around the electrode and to allow pore water in the soil to flow out from the cathode without pumping. The variation of settlement, shear strength, and voltage distribution during treatment was measured, and tube samples were recovered before and after treatment for laboratory tests. The results of field vane tests at different locations within the treated area and at different innes indicate that the undrained shear strength increased uniformly by approximately 30% for a period of 32 days throughout the depth of the electrodes. Concurrently, an average surface settlement of 50 mm was achieved. The total project cost, indicating that the design of the treatment system was efficient. It is evident, therefore, that substantial increase in strength as the treatment system was efficient. It is evident, therefore, that substantial increase in strength as well as general improvement in soil properties may be achieved by this improved version of electroosmosis. The elimination of pumping improved the economy of the process considerably. It is hoped

#### Field 8—ENGINEERING WORKS

ANALYSIS OF A SANITARY-EMBANKMENT FAILURE OVER THE RIO DE JANEIRO SOFT CLAY DEPOSIT.

CLAY IDEPOSIT.
Rio de Janeiro Bureau of Public Works (Brazil).
R. P. da Cunha, and W. A. Lacerda.
Canadian Geotechnical Journal CGJOAH, Vol.
28, No. 1, p 92-102, February 1991. 17 fig, 18 ref.

Descriptors: \*Clays, \*Embankments, \*Foundation failure, \*Hydraulic structures, \*Landfills, \*Soil mechanics, Case studies, Cohesion, Load distribution, Pore pressure, Rio de Janeiro, Sanitary landfills, Soil properties, Soil stabilization, Soil tests, Stability analysis, Strength, Stress.

An investigation was undertaken to analyze an embankment failure over a soft clay deposit in the district of Caju, Rio de Janeiro. The area has sanitary and rubble embankments. The main difficulty of the analysis lies in the indiscriminate filling in the region, which has led to a series of foundation failures, including under and around the embankment. Index tests were performed to obtain geotechnical characteristics and a profile of the soft clay deposit. Odometer tests, in situ and laboratory vane tests, standard penetration tests, and conventional triaxial tests were also carried out. Total stress calculations were used to interpret and back analyze the failure and also to obtain the mobilized shear strength at both the fill and clay foundations. It was concluded that the failure was caused by the land increase of a recent embankment composed predominantly of rubble material. This caused a pore pressure increase in the unconsolidated soft clay. It is believed that the effective pressures inside the clay had a magnitude similar to the maximum past pressure of the respective strata. The vane test results showed erratic variability of the undrained shear strength of this deposit. There was a mobilization of a certain amount of shear strength in the embankment body. With the assumption of a 35-degree friction angle for the embankment, the calculated cohesion had a magnitude of between 0-20 kPa. (Korn-PTT)

COMPARISON OF FIELD CONSOLIDATION WITH LABORATORY AND IN SITU TESTS. British Columbia Univ., Vancouver. Dept. of Civil

Engineering.
C. B. Crawford, and R. G. Campanella.
Canadian Geotechnical Journal CGJOAH, Vol. 28, No. 1, p 103-112, February 1991. 14 fig, 3 tab, 18 ref.

Descriptors: \*Embankments, \*Soil engineering, \*Soil mechanics, \*Soil properties, \*Soil stabilization, Compressibility, Consolidation, Field tests, In situ tests, Piezometers, Pore pressure, Soil analysis, Strength, Stress, Structural engineering.

The use of in situ tests to predict consolidation settlements is of considerable interest to foundation negineering practices. In recent years, theories and correlations have been developed in an effort to relate in situ test results to the magnitude and rate of soil consolidation as stress increases, but full-scale observations are required to assess their reliability. A series of settlement calculations was conducted for an earth embankment resting on the soft, compressible sediments of the Fraser River Delta in British Columbia. The calculations were made from laboratory consolidation tests and from in situ tests using a piezocone and a flat dilatometre. The calculated values were then compared with measured settlements. There was rather good agreement among the three methods of calculation, but the actual settlement was about 60% greater

than the average calculated value. The reasons for this discrepancy are not known. It is likely that a significant part of the measured settlement may have been due to lateral spreading under the shoulders of the fill in the very sensitive subsoil. Another possibility is that the construction of the sand drains caused disturbance of the subsoil and that this resulted in increased consolidation settlement. Although there is good agreement among the prediction methods, the comparison with observed settlement is not satisfactory. Further field research is needed to determine how movement occurs, both vertically and laterally, and laboratory studies on better soil samples are required to improve understanding of the material properties. (Korn-PTT)

PRESSURE OF CLAY BACKFILL AGAINST RETAINING STRUCTURES.

Surrey Univ., Guildford (England). Dept. of Civil Engineering. C. R. I. Clayton, I. F. Symons, and J. C. Hiedra-Cobo.

Canadian Geotechnical Journal CGJOAH, Vol. 28, No. 2, p 282-297, April 1991. 18 fig, 1 tab, 31 ref.

Descriptors: \*Backfill, \*Check structures, \*Retaining walls, \*Soil pressure, \*Structural engineering, Clay soils, Cohesive soils, Plasticity, Soil compaction, Soil water. Stress.

Most earth retaining structures require placement of backfill material adjacent to the wall. A study was made of the pressures exerted by clay backfills against retaining structures. The lateral pressures were developed during three main phases: placement, compaction, and burial; horizontal total stress reduction at constant moisture content; and swelling or consolidation under approximately constant vertical stress. Experimental data from laboratory and pilot-scale studies, using clays of intermediate and high plasticity, were used to assess the magnitude of the pressure changes in each phase. Laboratory experiments showed that the maximum horizontal total stress that can remain after compaction is a function of the undrained shear strength of the clay and of its plasticity. Results of pilot-scale experiments indicate horizontal total stresses at the end of construction of about 0.2 and 0.4 for the intermediate and high-plasticity clays, respectively. It was concluded that previously-developed theories for assessing the pressures on retaining walls developed by compaction of granular soils are inapplicable for cohesive soils. Compaction pressures do not become significant until the air void content of the fill is reduced to less than 15%. The results from a preliminary numerical study were used to provide an indication of the likely effects of plasticity and placement moisture content. For well-compacted low-plasticity clays (Pl < 30%) swelling of the fill is less likely indices up to about 40%, swelling problems can probably be avoided if the placement moisture content is greater than a critical value. For clays of higher plasticity the fill is likely to be barely trafficable at this critical moisture content and some swelling will need to be allowed for, at least near the top of a rigid retaining structure. DEEP-SEATED CONSOLIDATION SETTLE-MENTS IN THE FRASER RIVER DELTA. British Columbia Univ., Vancouver. Dept. of Civil

Engineering.
C. B. Crawford, N. R. McCammon, and R. C. Butler.

Butler.
Canadian Geotechnical Journal CGJOAH, Vol. 28, No. 2, p 298-303, April 1991. 7 fig, 3 ref.

Descriptors: \*Canada, \*Deltas, \*Foundation failure, \*Soil compaction, \*Structural engineering, \*Structural settlement, Alluvial plains, British Columbia, Sediment sampling.

During the past 35 years, two cement plants have been built along the south channel of the Fraser River delta near Vancouver, British Columbia, Canada, in an area where a compressible layer of marine sediments occurs to a considerable depth below a thick layer of alluvial sand. Three heavy silo structures at the two plants have experienced settlement since the plants' construction in 1956. In this area, it has not been possible to obtain sufficiently undisturbed samples for reliable consolidation tests, and it has been necessary therefore to employ in situ tests and site improvement techniques such as preloading and vibrocompaction for the design of subsequent foundations in the same region. In some cases, piles were used to redistribute heavy loads. Observations during the past 35 years have shown that most of the consolidation settlement has occurred in a deep layer of marine sediments and that it was largely completed within 10 years of the loading. The Narmada Sagar Dam, a concrete gravity structure under construction across the Narmada River in central India, will have a crest length of 653 m and a maximum height of 92 m. Geotechnical investigations were undertaken to evaluate the quality of the rock mass foundations and to recommend further core drilling to characterize the rock mass foundation. The foundation rock mass consists of quartzite intercalated with thin bands of siltstone, grits, and conglomerates. The analysis of the in situ permeability tests suggests that the relatively high permeability of the foundation rock mass is due to an interconnected network of water-conducting joints. It is suggested that the estimate of spacing and opening of the water-conducting joints may lead to useful estimates of the groutable volume of voids in the rock mass, and inclined drill holes are preferable for optimum grouting. A systematic study of six divided geostructural zones suggests that the foundation rocks are fair for the construction of a concrete gravity structure on hem. Shear zones are classified as very poor rock, as they consist of gougy, sheeted, and brecciated material. These zones will be more pervious to water flowing along it rather than being perpendicular to the channel. The properties of the green siltstone layers are very important for design purposes because it is clear that the strength of the foundation of green siltstone, which is the weakest material within the foundation rocks are competent and suitable for designing the proposed concrete gravity dam. The Narmada Rift in India has been regarded as a major crustal feature of ancient origin. This region

# Materials—Group 8G

has now assumed significance because many major and minor projects for irrigation and power are planned across the Narmada river and its tributaries. The course of the river is tectonically controlled in the sense that the river is flowing along the southern fault of the rift. A major part of the gravity 'low' north of the river, as seen by gravity gravity 'low' north of the river, as seen by gravity anomaly maps, is caused by downfaulting of the high-velocity layer from a depth of 8 to 13 km. At least one earthquake of magnitude 6.3 has been historically recorded in the Narmada river region, and reliable gravity maps are now freely available, so the concerned engineers should take into account all possible safety measures when constructing the newest Sagar Dam. Since precise prediction of earthquakes is not possible, new structures in this area should be designed that can withstand earthquakes of magnitude 6.5 or 7.0. (Fish-PTT) W91-10949

PREDICTING CONCRETE SERVICE LIFE IN CASES OF DETERIORATION DUE TO FREEZ-ING AND THAWING.
JAYCOR, Vicksburg, MS.
L. M. Bryant, and P. F. Mlakar.
Available from the National Technical Information Service, Springfield, VA. 22161. Army Corps of Engineers Technical Report REMR-CS-35, March 1991. Final Report. 108p, 40 fig, 2 tab, 10 ref, 2 append. DOA Contract No. DACW39-87-C-0059.

Descriptors: \*Concrete, \*Deterioration, \*Freeze-thaw tests, Concrete construction, Concrete test-ing, Data interpretation, Decomposition, Model studies, Seepage, Temperature.

A procedure for predicting the service life of non-air-entrained concrete subject to damage due to freezing and thawing has been developed which addresses both the known and uncertain qualities of the relevant material properties, environmental factors, and model of degradation due to freezing and thawing using a probabilistic method. Two important characteristics of this procedure are: (1) it rationally addresses the uncertainties inherent in degradation of mass concrete due to freezing and thawing; and (2) the procedure is mathematically straightforward for implementation by Corps of Engineers offices. From six candidate structures, two features were selected as case studies for applitwo features were selected as case studies for appli-cation of the procedure. These two features were the middle wall and the land wall at Dashields Lock. The procedure was applied using the avail-able data for each case study. One-dimensional and two-dimensional thermal analyses were used to determine the thermal response of each wall and the resulting probabilities of critical temperature. Simplified seepage analyses provided the probabil-ties of critical saturation. The annual probability plified seepage analyses provided the probabil-of critical saturation. The annual probability of damage and the predicted service life were determined from the joint probabilities of critical determined from the joint probabilities of critical temperature and critical saturation throughout the structure. Several important conclusions can be reached from this study. Current procedures for thermal modeling and analysis appear quite adequate for predicting temperatures in a concrete structure. Although 2-D analyses are better for determining complex thermal response, in many cases a series of much simpler 1-D analyses provide a very good estimation of temperatures. The external temperature inputs to a thermal analysis, ie., water and air temperatures, were shown to be well represented by sinusoidal curves. An examination of the temperature distribution for any point in the structure indicated that the primary contributor to uncertainty of response was the annual variation of temperature. This important observation permits the probabilistic analysis to use the results of only a single thermal analysis at the mean values of the input factors. The procedure, therefore, provides excellent agreement with observed damage due to freezing and thawing at the two sites studied. (Lantz-PTT)

NONLINEAR EARTHQUAKE RESPONSE OF CONCRETE GRAVITY DAM SYSTEMS. California Inst. of Tech., Pasade

B. El-Aldi.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-193924. Price codes: Al 0 in paper copy, AO in microfiche. Report No. EERL 88-02, 1989. 191p, 76 fig., 2 tab, 51 ref, 5 append. NSF Grant Nos. CEE81-19962, CEE83-17257, and CES-8619908.

Descriptors: \*Concrete dams, \*Dam failure, \*Dam stability, \*Earthquakes, \*Gravity dams, Cavitation, Cracks, Hydraulic structures, Hydrodynamics, Mathematical studies, Model studies, Reservoirs,

The earthquake response of concrete gravity dam systems is investigated with emphasis on the non-linear behavior associated with tensile concrete cracking and water cavitation. A single dammonolith is considered and assumed to respond independently as a two-dimensional system under monoitti is considered and assumed to respond independently as a two-dimensional system under plane stress conditions; the two-dimensional assumption is also extended to model the compressible water body impounded upstream of the dam. Standard displacement-based finite element techniques were used to spatially discretize the field equations and produce a single symmetric matrix equation for the dam-water system. Energy dissiequation for the dam-water system. Energy dissi-pation in the reservoir, through radiation in the infinite upstream direction and absorption at the bottom, is approximately accounted for, and a set of numerical examples is presented, to demonstrate the accuracy of the present formulation in model-ing the linear earthquake response of infinite reser-voirs. Water cavitation is modeled by a smeared approach which uses a bilinear pressure-strain rela-tion. It is shown that the water response becomes tion. It is shown that the water response becomes dominated by spurious high frequency oscillations upon closure of cavitated regions, and improved results can be obtained by using some stiffness-proportional damping in the water reservoir. As demonstrated in an example analysis of Pine Flat Dam (linear dam), cavitation occurs in the upper part of the reservoir along the dam face, unlike other investigations which show cavitated regions at considerable distances from the dam; both the tensile pressure cutoffs and compressive impacts have a minor effect on the dam response. Propagation of cracks is monitored in an interactive envinave a minor elect on the cam response. Propaga-tion of cracks is monitored in an interactive envi-ronment which uses an equivalent strength crite-rion and allows for user input; remeshing is avoid-ed. The algorithm adopted here produces narrow cracks (unlike many other investigations which show large zones of cracking) illustrating that cracking reduces the hydrodynamic pressures in the reservoir and, hence, reduces water cavitation.

SEISMIC FRACTURE ANALYSIS OF CON-CRETE GRAVITY DAMS.

Since the Hsinfengkiang dam in China and the Koyna dam in India experienced very similar severe cracking damage during strong earthquakes in 1962 and 1967, considerable attention has focused on evaluating the safety of existing dams and predicting the dynamic performance of newly designed concrete dams subjected to strong earthquakes. A numerical procedure has been developed for the evaluation of the fracture process of gravity dams during strong earthquakes. The Boundary Element Method (BEM) is used to discretize the dam reservoir system including the crack surfaces, and stress intensity factors at the crack tip are employed in a stage by stage procedure which simulates the crack extension. For each

stage of constant crack length the mode superposition technique is applied. This is made possible by simulating the impact process of crack closing by a load pulse applied at the contact points which permits the assumption that the structural stiffness is unchanged. To verify the proposed procedure, a cantilever beam model structure made of gypsum was tested on a shaking table. Good correlation with the numerical results was obtained, from which it is concluded that the procedure can be employed for evaluation of the crack propagation process in concrete structures subjected to dynamic loadings. Flood control, Grasses, Porosity, Stream banks. On the banks of the River Cynon in Aberdare, South Wales, seven designs of flood revetment blocks were tested for resistance to penetration and displacement by Reynoutria japonica, an introduced alien now widespread on river banks in some areas. With the subsequent failure of all designs tested, the testing of a new block was undertaken. The problem with the current block types is caused by the large vertical macro-voids, which are filled with soil and whilst providing a suitable habitat for colonization by small herbaceous plants and grasses, also enable established plants to produce new shoots which may penetrate these voids. The new design performed better than the current designs because it had both a microporous structure and interlocking edges which prevented intra and interblock growths of R. japonica. However, despite the growth of grasses on the miniature blocks described, an aesthetically pleasing grass surface failed to appear on the new design in field trials, which was a result of a long dry summer in 1989 killing the grass seedlings 1 week after emergence. THERMAL-PULSE FLOWMETER FOR MEAS-URING SLOW WATER VELOCITIES IN BORE-HOLES

Geological Survey, Denver, CO. A. E. Hess.

A. E. ress.

Available from the US Geological Survey, Books and Open-File Reports Section, Box 25425, Federal Center, Denver, Co 80225-0425. Open-File Report 87-121, 1990. 70p, 49 fig, 4 tab, 17 ref.

Descriptors: \*Borehole geophysics, \*Boreholes, \*Flow velocity, \*Flowmeters, \*Instrumentation, \*Measuring instruments, \*Thermal-pulse flowmeters, Data acquisition, Handbooks, Hydraulic

The US Geological Survey has developed an all electronic, thermal-pulse flowmeter for measuring slow axial-velocities of water in boreholes. The flowmeter has no moving parts, but senses the movement of water (or any other fluid) by a thermal-tag/trace-time technique. In the configuration shown in this report, the flowmeter can measure water velocities ranging between about 0.1 to 20 ft/min, can resolve water velocity differences as

#### Field 8—ENGINEERING WORKS

#### **Group 8G—Materials**

small as 0.03 ft/min, and distinguish between upward and downward flow. Two diameters of interchangeable flow sensors are described--the smaller sensor is 1.75 inches in diameter including the collapsed centralizer, and the larger is 2.75 the collapsed centralizer, and the larger is 2.75 inches in diameter with collapsed centralizer. The flowmeter probe is 48 inches long and has been tested and used in tubes and boreholes with diameters ranging from 2 to 10 inches. The flowmeter also should be useful for measuring slow velocity flows in larger diameter boreholes, though for best accuracy it should be calibrated for flow at the diameter of the horehole in which it is to be used diameter of the borehole in which it is to be used. The flowmeter probe has been designed to withstand a water pressure depth of 10,000 feet. The report includes a description of the operation of the flowmeter, functional diagrams, mechanical drawings, and electronic schematics for both the flowmeter probe and surface electronics. Lists of parts and materials, and instructions for fabrica-tion, assembly, and calibration also are included. tion, assembly, and calibration also are included. These diagrams and lists should be adequate to permit the construction and use of a thermal-pulse flowmeter system by those skilled in machining and fabrication, electronics fabrication, and borehole metrology. Recent advances in ground-probing radar instru-mentation have allowed the collection of large volumes of digital data. Such data sets are amena-ble to modern data processing techniques both to increase geological resolution and to enhance data presentation. The close similarity between groundradar data and seismic data suggests that processing techniques that have been used in the seismic industry could be applied to radar data. The tailings pond at the Echo Bay Mines Limited Lupin mine, near Contwoyto Lake, Northwest Territories, employs several small frozen-core contain-ment dams to enclose a small watershed and to retain the mine tailings fluid. The freezing of the interiors of the dams, coupled with the underlying permafrost in the subsurface were expected to create an impermeable frozen barrier to fluid flow. During the summer of 1986, ground-probing radar surveys were conducted over several of the dams where tailings water was seeping into the sur-rounding environment. A ground-probing radar profile was deconvolved using the common prediction-error filter, which assumes a white power spectrum for the reflections, and a filter that assumes a spectrum proportional to spatial frequency. The results of the study revealed that the prediction-error filter found three of four buried presuction-error filter found three of four buried pipes which had not been visible in the undecon-volved section. All four pipes were found with the use of a second filter. (Korn-PTT) W91-10782

The development of coastal fisheries has been an important priority in Japan. Changes of oceanic conditions as a result of a man-made structure (MARITEX) for upwelling were investigated in Bungo Channel, in the Seto Inland Sea, Japan. The structure, 10 m high and 20 m wide, was set 50 m below the ocean surface in order to induce upwelling at the eastern part of the Bungo Channel in the autumn of 1987. Intensive field observations were carried out before and after the installation of the carried out before and after the installation of the structure. Nutrients, chlorophyll a and the biomass of zooplankton increased after the structure's installation. Net flow, averaged over fifteen days was directed to the southeast with a speed of about 15 cm/sec, and was not changed by the installation fMARITEX. The number of species and population size decreased after the MARITEX installation, but average hold vize increased. Long-terms of the structure of t tion, but average body size increased. Long-term investigations are needed to assess the impact over time. (Brunone-PTT)

PACIFIC SALMON AT THE CROSSROADS: STOCKS AT RISK FROM CALIFORNIA, OREGON, IDAHO, AND WASHINGTON.

W. Nehlsen, J. E. Williams, and J. A. Lichatowich. Fisheries (Bethesda) FISHDN, Vol. 16, No. 2, p 4-21, March/April 1991. 2 tab, 81 ref.

Descriptors: "California, "Endangered species, "Fish management, "Idaho, "Oregon, "Salmon, Species composition, "Washington, Agriculture, Fish conservation, Fish hatcheries, Habitat restoration, Habitats, Hydroelectric power.

The American Fisheries Society herein provides a list of depleted Pacific salmon, steelhead, and searun cutthroat stocks from California, Oregon, Idaho, and Washington, to accompany the list of rare inland fishes reported previously. The list includes 214 native naturally-spawning stocks: 101 at high risk of extinction, 58 at moderate risk of as ingir iss of special concern, and one classified as threatened under the Endangered Species Act of 1973 and as endangered by the state of Califor-nia. The decline in native salmon, steelhead, and nia. In decline in native samon, steelnead, and sea-run cutthroat populations has resulted from habitat loss and damage, and inadequate passage and flows caused by hydropower, agriculture, log-ging, and other developments; overfishing, primar-ily of weaker stocks in mixed-stock fisheries; and negative interactions with other fishes, including nonnative hatchery salmon and steelhead. While nonnative nationery samon and steelnead. While some attempts at remedying these threats have been made, they have not been enough to prevent the broad decline of stocks along the West Coast. A new paradigm that advances habitat restoration and ecosystem function rather than hatchery production is needed for many of these stocks to survive and prosper into the next century. HYDRAULICS OF CULVERT FISHWAYS IV: SPOILER BAFFLE CULVERT FISHWAYS. Alberta Univ., Edmonton, Dept. of Civil Engi-

N. Rajaratnam, C. Katopodis, and S. Lodewyk. Canadian Journal of Civil Engineering CJCEB8, Vol. 18, No. 1, p 76-82, February 1991. 13 fig, 1 tab, 8 ref.

Descriptors: \*Culvert fishways, \*Fish passages, \*Hydraulics, Comparison studies, Design criteria, Performance evaluation, Spoiler baffles, Weirs.

A culvert with special provisions to make it passable by fish is referred to as a culvert fishway. Several devices have been developed to improve the fish-passing capacity of culverts. An experimental study was conducted on the hydraulics of culvert fishways with spoiler baffles. Four designs were studied with heights of the baffles equal to 0.99D and 0.15D and longitudinal spacings of 0.53D and 1.06D, where D is the diameter of the culvert. Design equations were developed relating culvert. Design equations were developed relating the flow depth to the flow rate, diameter, and slope of the culvert for each baffle design. Expres-sions also were found for the barrier velocity. Two sions also were found for the barrier velocity. Two designs, both using alternating sets of three and four baffles, were quite effective in providing larger depths in the pools between baffles and reduced barrier velocities at the baffles. Compared to simpler baffle systems (e.g., weir), the spoiler baffle system would be more expensive to install, unless the baffle plates were installed during the construction of the culvert itself. (Rochester-PTT) W91-11279

ASSESSING STREAM VALUES: PERSPEC-TIVES OF AQUATIC RESOURCE PROFES-SIONALS.

A multiattribute judgment technique was used to identify features of streams and rivers that confer

Specialized Information Center Services—Group 10D

ecological and fishery values as perceived by aquatic resource professionals. Four groups of pro-fessionals were surveyed: (1) fishery managers fessionals were surveyed: (1) fishery managers from Virginia's fisheries management agency; (2) aquatic biologists from Virginia's water quality regulation agency; (3) fishery managers from throughout the USA; and (4) fish ecologists from throughout the USA. Each professional assigned scores indicating value to a series of hypothetical streams that varied on the basis of six predetermined factors: species richness, importance to rare or endemic species, percent of habitat modified, water quality, percent of riparian zone forested, and fish abundance. Multiple linear regression was used to examine relationships between the varying factors and the value scores assigned by professionfactors and the value scores assigned by profession-als. Importance to rare and endemic species and species richness were major determinants of pereived ecological value, whereas fishery value was ceived ecological value, whereas fishery value was largely determined by species composition, aesthetic quality, and fish size. Although value perspectives were generally similar among groups of professionals, perspectives of fishery value were more discordant than perspectives of ecological value. It is suspected that variation in fisheries managers' views of fishery-related value results from the lark of a cohesive framework for fisheries. managers' views of fishery-related value results from the lack of a cohesive framework for fisheries management policy. This work illustrates how analytical techniques developed in the social sciences may help fishery managers assign priorities among their research and management activities. Converting implicit knowledge into explicit policy criteria can improve efficiency and public acceptance of management strategies. (Medina-PTT) W91-11425

# PRODUCTION OF CHIRONOMID LARVAE IN CULTURING MEDIA OF VARIOUS ORGANIC WASTES,

Kalyani Univ. (India). Dept. of Zoology.

B. B. Jana, and G. P. Pal. Limnologica LMNOA8, Vol. 21, No. 1, p 281-285, October 1990. 2 fig, 2 tab, 18 ref.

Descriptors: \*Culture media, \*Fish farming, \*Fish Food, \*Midges, \*Waste utilization, Animal wastes, Aquatic insects, Biomass, Carbon, Cattle, Food chains, Food-processing wastes, Larval growth stage, Manure, Nitrogen, Population density, Poultry, Productivity, Rice.

Various organic wastes were examined as media for the secondary production of chironomia larvae, which form an important link in the food chain of many cultivable fishes. Estimates of population number, biomass, and production of three size classes of chironomid larvae were obtained size classes of chironomid larvae were obtained from culturing media comprising mustard oil cake, nohua oil cake, cow dung, poultry waste, and rice bran. The large, medium, and small size classes occurred in maximal numbers in mustard oil cake, rice bran, and poultry waste, respectively. Monthly mean production (P) ranged from 5.4 to 10.0 g/sq m, while total biomass (B) varied between 5.7 and 15.8 g/sq m. Among the culture media, the average P/B coefficient was highest for pond water (1.3) and lowest for mustard oil cake (0.42). The high level of production in the rice bran medium may be due to its higher C/N ratio (prepared aquadte medium 2.43, dry manure 23.0) than the other culture media. Because of the dominance of small and medium-sized individuals in the cow dung medium, a relatively total low biomass was dung medium, a relatively total low biomass was expected in this medium compared with the others. The percent distribution of the three size classes of chironomid populations leads to a similar conclusion. Since production in the rice bran, cow dung, and poultry waste media was markedly higher than in the others, the former media seem to be most useful for mass production of chironomid larvae. # OVERVIEW OF U.S. GEOLOGICAL SURVEY WATER-RESOURCES INFORMATION PRO-GRAMS.

N. Lopez.

IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p 87-91, 1 tab, 2 ref.

Descriptors: \*Groundwater quality, \*Information Descriptors: "Croundwater quanty, "Information systems, "Nonpoint pollution sources, "US Geological Survey, Agricultural chemicals, Data storage and retrieval, Geochemistry, Geohydrology, National Water Quality Assessment Progra, Regional Aquifer System Analysis, Research.

The Geological Survey maintains the largest single source of groundwater resources and related earth science information in the United States. Much of this information comes from the various selected activities of the Water Resources Division of the devines of the water accounts Division of the Geological Survey. The Regional Aquifer Systems Analysis (RASA) Program has produced more than 600 reports, hydrologic investigations atlases, and scientific articles between 1978 and 1988 on 14 and scientific arricles between 1978 and 1986 on 14 of the 28 aquifer systems originally identified for study. The National Water Quality Assessment Program (NAWQA), begun in 1986, is designed to define the current status of water quality and to identify and evaluate changes in it. The National Research Program is organized into six major research disciplings, water chamistry, anotheristic than the control of the program o search disciplines: water chemistry, geochemistry, groundwater hydrology, surface-water hydrology, geomorphology and sediment transport, and cology. The research program supports all other activigy. The research program supports an other activi-ties of the Survey and supports related work in other organizations. A major objective of this pro-gram is research on the fate and transport of natu-ral and man-made contaminants, especially agricul-tural chemicals, in groundwater. The Geological Survey maintains all data on their mainframe computer in Reston. Information is transferred to dis-trict offices by telecommunications. (See also W91-11162) (Rubinstein-PTT) in Reston. AGRISOURCE: THE INFORMATION SYSTEM FOR CROP TECHNOLOGY. REACH/AgriSource, Cenex/Land O'Lakes, PO Box 64089, St. Paul, MN 55164-0089. J. S. Ahlrichs.

J. S. Aniricas.
IN: Agrichemicals and Groundwater Protection: Resources and Strategies for State and Local Management. Freshwater Foundation, Navarre, Minnesota. 1989. p. 353-355.

Descriptors: \*Agricultural chemicals, \*Agriculture, \*Computers, \*Hazardous materials, \*Information systems, \*Nonpoint pollution sources, \*Water pollution prevention, Computer programs, Data processing, Databases, Decision making.

AgriSource is a communication and information system for crop technology developed by Cenex/Land O'Lakes, a large regional farm cooperative. It was developed on the foundation that numerous information providers are trying, sometimes with limited success, to get agronomic information to fertilizer and chemical dealers and farmers in a fertilizer and chemical dealers and farmers in a timely manner. It was also developed on the foundation that these groups often cannot get the up-to-date information they need when they need it. Agronomists and other decision makers at fertilizer and chemical dealerships are the primary influence affecting a farmer's or other end user's product application and use decisions. These decision makers are the true target audience of most government, industry, university and extension personnel. AgriSource provides an easy way to directly reach this target audience each day. With the AgriSource communication network, Cenex/Land O'Lakes has gone to primary information suppliers (chemical companies, soil test labs, government and industry) and arranged for them to enter their information in a standard, organized format. A computer is installed at each information supplier to enter and maintain their database. Fertilizer and computer is installed at each information supplier to enter and maintain their database. Fertilizer and chemical dealers and other professionals needing timely and up-to-date agronomic information subscribe to these databases. Each night a personal computer located at Cenex/Land O'Lakes updates and sorts new information provided by the information supplier. To install AgriSource the user must provide a computer while Cenex/Land O'Lakes provides all of the AgriSource programs and databases. (See also W91-11162) (Korn-PTT) W91-11196

Networks.

The National Water Data Exchange (NAWDEX) is a national program to assist users of water data or water-related data in identifying, locating, and acquiring needed data. A variety of data, indexing, assistance and referral services are provided through a nationwide network of Assistance Centers located in 45 States and Puerto Rico. The program is centrally managed and coordinated by a NAWDEX Program Office located within the US Geological Survey in Reston, Virginia. NAWDEX is a national confederation consisting of member organizations from all sectors of the water data community including Federal, State, local governmental, academic, interstate, and private organizations. Foreign organizations are also invited to become affiliated with the program. This Directory provides the names, addresses, and telephone numbers of all NAWDEX member organizations and their designated NAWDEX representatives. (See also W91-11575) (Lantz-PTT)
